

HOW MANY ITERATIONS ARE SUFFICIENT FOR SEMIPARAMETRIC ESTIMATION?

September 17, 2010

BY GUANG CHENG*

Purdue University

A common practice in obtaining a semiparametric efficient estimate is through iteratively maximizing the (penalized) log-likelihood w.r.t. its Euclidean parameter and functional nuisance parameter via some numerical algorithm. The purpose of this paper is to provide a formula in calculating the minimal number of iterations k^* needed to produce an efficient estimate $\widehat{\theta}_n^{(k^*)}$ from a theoretical point of view. We discover that (a) k^* depends on the convergence rates of the initial estimate and nuisance estimate; (b) more than k^* iterations, i.e., k , will only improve the higher order asymptotic efficiency of $\widehat{\theta}_n^{(k)}$; (c) k^* iterations are also sufficient for recovering the estimation sparsity in high dimensional data. These general conclusions hold, in particular, when the form of the efficient score function is unknown, and apply to semiparametric models estimated under various regularizations, e.g., kernel or penalized estimation. This paper provides a first general theoretical justification for the “one-/two-step iteration” phenomena observed in the literature, and may be useful in reducing the bootstrap computational cost for the semiparametric models.

Keywords and phrases: k -step Estimation, Semiparametric Models, Generalized Profile Likelihood, Newton Raphson Algorithm, Higher Order Asymptotic Efficiency.

1. Introduction. Semiparametric models indexed by a Euclidean parameter of interest $\theta \in \Theta \subset \mathbb{R}^d$ and a possibly infinite-dimensional nuisance parameter $\eta \in \mathcal{H}$ are proven to be useful in a variety of contexts, e.g., [1, 4, 8, 19, 24, 27, 29, 34, 37]. The semiparametric MLE for θ can be viewed as a solution of the implicitly defined efficient score function whose nonparametric estimation is only possible in some special cases, see [21, 24]. Therefore, it is generally hard to solve the MLE from the efficient score function analytically or numerically. A common practice is to maximize the log-profile likelihood, i.e.,

$$(1) \quad \log pl_n(\theta) = \sup_{\eta \in \mathcal{H}} \log lik_n(\theta, \eta),$$

where $lik_n(\theta, \eta)$ is the likelihood given n data, via some optimization algorithm. For example, the Newton-Raphson algorithm is applied to the partial likelihood of the Cox model in the software **R** (with the command *coxph*).

A general algorithm of obtaining a semiparametric efficient estimate of θ is to iteratively maximize the log-likelihood w.r.t. θ and η as follows:

General Semiparametric Iterative Estimation Algorithm

- I. Identify an initial estimate $\hat{\theta}_n^{(0)}$;
- II. Construct the corresponding nuisance estimate $\hat{\eta}(\hat{\theta}_n^{(0)})$ either by pure nonparametric approach, e.g., isotonic estimation, or under some regularization, e.g., kernel or sieve estimation;
- III. Apply the Newton-Raphson (NR) or other optimization algorithm to

$$(2) \quad \hat{S}_n(\theta) = \log lik_n(\theta, \hat{\eta}(\theta)),$$

at $\theta = \hat{\theta}_n^{(0)}$ to obtain $\hat{\theta}_n^{(1)}$;

IV. Repeat steps II-III k^* iterations until

$$|\widehat{S}_n(\widehat{\theta}_n^{(k^*)}) - \widehat{S}_n(\widehat{\theta}_n^{(k^*-1)})| \leq \epsilon$$

for some pre-determined sufficiently small ϵ .

Note that $\widehat{S}_n(\theta)$ defined in (2) is also called the generalized profile likelihood in [36]. If $\widehat{\eta}(\theta)$ is the nonparametric MLE (NPMLE) for any fixed θ , then $\widehat{S}_n(\theta)$ is just the profile likelihood defined in (1). The above likelihood estimation procedure or its M-estimation analog has been extensively implemented in the literature. Here is an incomplete list: (i) Odds-Rate Regression Model under Survival Data, e.g., [24, 29]; (ii) Logistic Regression with Missing Covariates, e.g., [34]; (iii) Semiparametric Regression under Shape Constraints, e.g., [4, 11]; (iv) Generalized Partly Linear (Single Index) Model, e.g., [8, 19]; (v) Conditionally Parametric Model, e.g. [36, 37], (vi) Semiparametric Transformation Model, e.g., [27]. In addition, the above iterative procedure can also be adapted to the penalized estimation and selection of the semiparametric models by using a different criterion function than (2), see [7, 16, 28]. We will discuss that scenario in Section 4.2. However, in all the above papers, k^* or ϵ is *arbitrarily* chosen in practice.

The main purpose of our paper is to answer “How Many Iterations Do We Really Need in Semiparametric Estimation?” from a *theoretical* point of view. We provide a general formula in calculating the minimal number of iterations k^* needed to produce a semiparametric efficient $\widehat{\theta}_n^{(k^*)}$. Specifically, we discover that (a) k^* depends on the convergence rates of $\widehat{\theta}_n^{(0)}$ and $\widehat{\eta}(\theta)$; (b) more than k^* iterations, i.e., k , will not change the limiting distribution of $\widehat{\theta}_n^{(k)}$, but will improve its higher order asymptotic efficiency; (c) k^* iterations are also sufficient for recovering the estimation sparsity under

high dimensional data. Note that the convergence rate of the regularized estimator $\hat{\eta}(\theta)$ is determined by the related smoothing parameters, e.g., the bandwidth order in kernel estimation. These general conclusions apply to semiparametric models estimated under various regularizations, e.g., kernel or penalized estimation. We want to point out that our construction of the semiparametric efficient estimate does not require knowing the form of the implicitly defined efficient score function, and thus applies to more general classes of semiparametric models considered in the literature, i.e., [5, 21]. Our theoretical results extend the one-step MLE results in parametric models, i.e., [25], to account for the presence of an infinite-dimensional nuisance parameter. A general strategy of identifying $\hat{\theta}_n^{(0)}$ with proper convergence rate is also considered. The technical challenge in this paper is that $\hat{S}_n(\theta)$ in practice may not have an explicit form or is not continuous/smooth.

As far as we are aware, our paper provides a first general theoretical justification for the “one-/two-step iteration” phenomenon, i.e., $k^* = 1, 2$, observed in the semiparametric literature. However, we find that more iterations are absolutely necessary if η is estimated at a very slow rate. For example, we need 8 iterations to achieve the efficiency in conditionally exponential models, see Table 3. Moreover, our results are readily extended to the bootstrap estimation by combining with the most recent bootstrap consistency results obtained for semiparametric models in [16]. Therefore, we expect to significantly reduce bootstrap computational cost, which is very high in semiparametric models, after knowing k^* for each bootstrap sample. See [3] for similar ideas applied to the parametric models. Due to the space limitation, we only consider the NR algorithm in this paper, but notice that

the extensions to the slight modifications of NR are possible by considering the discussions in Page 534 of [33].

Section 2 provides some necessary background material on the semiparametric estimation. In Section 3, we consider the semiparametric maximum likelihood estimation in which $\widehat{S}_n(\theta)$ is the possibly nonsmooth profile likelihood (1). In Section 4, we consider the semiparametric estimation under two types of regularization, i.e., kernel estimation and penalized estimation, in which $\widehat{S}_n(\theta)$ is smooth. In this section, we also consider the sparse and efficient estimation of the partial linear models as an important application of penalized estimation. In Section 5, we propose two grid search algorithms for identifying initial estimate whose convergence rate will be rigorously proven. Several semiparametric models ranging from survival models, mixture models to conditionally exponential models are treated to illustrate the applicability of our theories. All the proofs are postponed to the Appendix.

2. Preliminary. We assume that the data X_1, \dots, X_n are i.i.d. throughout the paper. In what follows, we first briefly review the concepts of the efficient score function and the least favorable curve (LFC), and then relate the estimation of LFC to that of θ as discussed in [36].

The score functions for θ and η are defined as, respectively,

$$\begin{aligned} \dot{\ell}_{\theta, \eta}(X_i) &= \frac{\partial}{\partial \theta} \log \text{lik}(X_i; \theta, \eta), \\ (3) \quad A_{\theta, \eta} h(\theta, \eta)(X_i) &= \frac{\partial}{\partial t} \Big|_{t=0} \log \text{lik}(X_i; \theta, \eta(t)), \end{aligned}$$

where $h(\theta, \eta)$ is a “direction” along which $\eta(t) \in \mathcal{H}$ approaches η as $t \rightarrow 0$. $A_{\theta, \eta} : \mathbf{H} \mapsto L_2^0(P_{\theta, \eta})$ is the score operator for η , where \mathbf{H} is some index set. The efficient score function $\widetilde{\ell}(\theta, \eta)$ is defined as the residual of the projection

of $\dot{\ell}_{\theta,\eta}$ onto the tangent space $\mathcal{T} = \{A_{\theta,\eta}H = (A_{\theta,\eta}h_1, \dots, A_{\theta,\eta}h_d)' : h_j \in \mathbf{H} \text{ for } j = 1, \dots, d\}$. Therefore, we can write the efficient score function as

$$(4) \quad \tilde{\ell}(\theta, \eta) = \dot{\ell}_{\theta,\eta} - A_{\theta,\eta}H^*(\theta, \eta),$$

where

$$A_{\theta,\eta}H^*(\theta, \eta) = \arg \min_{A_{\theta,\eta}H \in \mathcal{T}} E_{\theta,\eta} \|\dot{\ell}_{\theta,\eta} - A_{\theta,\eta}H\|^2.$$

We call $H^*(\theta, \eta)$ as the least favorable direction. For simplicity, we denote $\tilde{\ell}(\theta_0, \eta_0) = \tilde{\ell}_0$ and $H^*(\theta_0, \eta_0) = H_0^*$. The variance of $\tilde{\ell}_0$ is defined as the efficient information matrix \tilde{I}_0 . The inverse of \tilde{I}_0 is shown to be Cramér-Rao bound for estimating θ in the presence of an infinite dimensional η , see [6].

A main idea of estimating θ is to reduce a high dimensional semiparametric model to a low dimensional random submodel of the same dimension as θ called the least favorable submodel (LFS). The LFS can be constructed as $t \mapsto \log \text{lik}(t, \eta(t))$ and satisfies

$$(5) \quad \frac{\partial}{\partial t} \big|_{t=\theta_0} \log \text{lik}(t, \eta(t)) = \tilde{\ell}_0.$$

The $\eta(t)$ in the LFS is called as least favorable curve. Under regularity conditions, it is shown that

$$(6) \quad \eta(t) = \arg \sup_{\eta \in \mathcal{H}} E \log \text{lik}(t, \eta) \quad \text{for any fixed } t \in \Theta,$$

and thus

$$(7) \quad \eta(\theta_0) = \eta_0.$$

By (6) and standard arguments, we can establish that the maximizer of

$$S_n(\theta) \equiv n\mathbb{P}_n \log \text{lik}(\theta, \eta(\theta))$$

is semiparametric efficient. In addition, based on (5), we can derive that

$$(8) E \left(\frac{\partial}{\partial t} \Big|_{t=\theta_0} \log \text{lik}(t, \eta(t)) \right)^{\otimes 2} = -E \left(\frac{\partial^2}{\partial t^2} \Big|_{t=\theta_0} \log \text{lik}(t, \eta(t)) \right) = \tilde{I}_0.$$

Recall that $\hat{S}_n(\theta) = n\mathbb{P}_n \log \text{lik}(\theta, \hat{\eta}(\theta))$. Define

$$(9) \quad \hat{\theta}_n = \arg \sup_{\theta \in \Theta} \hat{S}_n(\theta).$$

In view of the above discussions, we can show that $\hat{\theta}_n$ is semiparametric efficient by standard arguments if $\hat{\eta}(\theta)$ is a consistent estimate of $\eta(\theta)$. The technical derivations in the above can be referred to Section 4 of [36]. However, the form of $\hat{\theta}_n$ depends on how we estimate the abstract $\eta(\theta)$ defined in (6). For example, $\hat{\theta}_n$ is just the semiparametric MLE if $\hat{\eta}(\theta)$ is the well defined NPMLE. When the infinite dimensional \mathcal{H} is too large, we may consider estimating $\eta(\theta)$ under some form of regularization, e.g., penalization. We want to point out that the convergence rate of $\hat{\eta}(\theta)$ is determined by the size of the parameter space \mathcal{H} in terms of its entropy number and the smoothing parameters associated with regularization methods (if used), e.g., smoothing parameter in penalized estimation.

In the following, we will consider two types of $\hat{\theta}_n$ defined in (9) according to the way we estimate $\eta(\theta)$: (i) pure nonparametric estimation in Section 3; (ii) nonparametric estimation under regularization in Section 4. We define $R_n \asymp r_n$ if $r_n/M \leq R_n \leq r_n M$ for some $M \geq 1$. Denote some neighborhood of θ_0 as $\mathcal{N}(\theta_0)$. Let v_i denote the i -th unit vector in \mathbb{R}^d . Define the i -th $((i, j)$ -th) element of a vector V (Matrix M) as V_i (M_{ij}). For a tensor $T^{(3)}(\theta)$, we define $V^T \otimes T^{(3)}(\theta) \otimes V$ as a d -dimensional vector whose i -th element equals $V^T (\partial^2 / \partial \theta^2) (\dot{T}(\theta))_i V$. Denote $\text{int}[x]$ and $\widetilde{\text{int}}[x]$ as the smallest nonnegative

integer $\geq x$ and $> x$, respectively. The norm applied to any Euclidean parameter is the Euclidean norm.

3. Semiparametric Maximum Likelihood Estimation. In this section, we consider the maximum likelihood estimation of θ which corresponds to the case that (i) $\hat{\eta}(\theta)$ is the NPMLE for η given any fixed θ and (ii) $\hat{S}_n(\theta) = \log pl_n(\theta)$. The nonparametric estimation (without any regularization) of $\eta(\theta)$ is often feasible when η is under shape restrictions, e.g. the monotone cumulative hazard function. In general, the profile likelihood does not have a closed form since it is defined as a supremum over an infinite dimensional parameter space, see (1). In practice, it can only be calculated numerically, e.g., via the iterative convex minorant algorithm [24] when η is monotone. In the end, we will present two examples representing a class of survival models and a class of mixture models.

In the profile likelihood framework, we write $\hat{\theta}_n^{(k)}$ in step (III) as follows:

$$(10) \quad \hat{\theta}_n^{(k)} = \hat{\theta}_n^{(k-1)} + \left[\hat{I}_n(\hat{\theta}_n^{(k-1)}, t_n) \right]^{-1} \hat{\ell}_n(\hat{\theta}_n^{(k-1)}, s_n),$$

where

$$(11) \quad \left[\hat{\ell}_n(\theta, s_n) \right]_i = \frac{\log pl_n(\theta + s_n v_i) - \log pl_n(\theta)}{n s_n},$$

$$(12) \quad \begin{aligned} \left[\hat{I}_n(\theta, t_n) \right]_{i,j} &= - \frac{\log pl_n(\theta + v_i t_n + v_j t_n) + \log pl_n(\theta)}{n t_n^2} \\ &+ \frac{\log pl_n(\theta + v_i t_n) + \log pl_n(\theta + v_j t_n)}{n t_n^2}, \end{aligned}$$

with step sizes $s_n, t_n \rightarrow 0$. Obviously, the form (10) implies that we apply the NR algorithm in step (III). We use the numerical derivatives of $\log pl_n(\theta)$ in (10) because its smoothness and differentiability is usually unknown. In view

of (5) and (8), we show that (11) and (12) (also called as the observed information in [30]) are the estimates of $\mathbb{P}_n \tilde{\ell}_0$ and \tilde{I}_0 , respectively, see Lemma A.1 in Appendix. Here, we estimate $\tilde{\ell}_0$ and \tilde{I}_0 without knowing their forms.

The convergence of $\hat{\theta}_n^{(k)}$ to $\hat{\theta}_n$, which is exactly the maximizer of $\log pl_n(\theta)$, as $k \rightarrow \infty$ is guaranteed by the asymptotic parabolic form of $\log pl_n(\theta)$ proven in [31]. However, to figure out the minimal number of iterations k^* such that $\|\hat{\theta}_n^{(k^*)} - \hat{\theta}_n\| = o_P(n^{-1/2})$, we need to make use of the second order asymptotic quadratic expansion of $\log pl_n(\theta)$ derived in [14]. This asymptotic expansion holds under the following convergence rate Condition (13) and least favorable submodel Conditions M1-M4 specified in Appendix. We assume that, for any random sequence $\tilde{\theta}_n \xrightarrow{P} \theta_0$ and the largest $1/4 < r \leq 1/2$,

$$(13) \quad \|\hat{\eta}(\tilde{\theta}_n) - \eta_0\| = O_P(\|\tilde{\theta}_n - \theta_0\| \vee n^{-r}),$$

where $\|\cdot\|$ is some norm in \mathcal{H} . For simplicity, we call r as the convergence rate of the nuisance parameter η . The above range of r holds in regular semiparametric models, which we can define without loss of generality to be models where the entropy integral converges. Theorems 3.1-3.2 in [30] can be applied to calculate the convergence rate (13).

Now we present our first main Theorem, i.e., Theorem 1. We first give an explicit formula (15) in calculating the stochastic order of $\|\hat{\theta}_n^{(k)} - \hat{\theta}_n\| = O_P(n^{-S(\psi, r, k)})$, where $\hat{\theta}_n^{(0)}$ is assumed to be n^ψ -consistent. Based on (15), we figure out the value of k^* in (16). In the proof of Theorem 1, we use the optimal step sizes in (11) and (12) at each iteration, under which the fastest

convergence rate can be achieved, see the discussions in Remark 2. Let

$$\begin{aligned} S_1(\psi, k) &= \psi(3/2)^k \text{ and } S_2(\psi, r, k) = 2r + 2^{-k}(\psi - 2r), \\ K_1(\psi, r) &= \text{int} \left[\frac{\log(r/\psi)}{\log(3/2)} \right] \text{ and } K_2(\psi, r) = \text{int} \left[\frac{\log((2r - \psi)/(2r - 1/2))}{\log 2} \right], \\ \tilde{S}_1(\psi, r) &= S_1(\psi, K_1(\psi, r)) \text{ and } \tilde{K}_2(\psi, r) = K_2(\tilde{S}_1(\psi, r), r). \end{aligned}$$

Define

$$S(\psi, r, k) = \begin{cases} S_1(\psi, k) & k \leq K_1(\psi, r) \\ r + 1/4 & k \geq K_1(\psi, r) + 1 \end{cases}$$

if $\tilde{S}_1(\psi, r) \geq 1/2$, and

$$S(\psi, r, k) = \begin{cases} S_1(\psi, k) & k \leq K_1(\psi, r) \\ S_2(\tilde{S}_1(\psi, r), r, k - K_1(\psi, r)) & K_1(\psi, r) < k \leq K_1(\psi, r) + \tilde{K}_2(\psi, r) \\ r + 1/4 & k \geq K_1(\psi, r) + \tilde{K}_2(\psi, r) + 1 \end{cases}$$

if $r \leq \tilde{S}_1(\psi, r) < 1/2$.

THEOREM 1. *Suppose that Conditions M1-M4 and (13) hold. If the MLE $\hat{\theta}_n$ is consistent and \tilde{I}_0 is nonsingular, then we have*

$$\begin{aligned} (14) \quad \sqrt{n}(\hat{\theta}_n - \theta_0) &= \frac{1}{\sqrt{n}} \sum_{i=1}^n \tilde{I}_0^{-1} \tilde{\ell}_0(X_i) + O_P(n^{-2r+1/2}) \\ &\xrightarrow{d} N(0, \tilde{I}_0^{-1}). \end{aligned}$$

Let $\hat{\theta}_n^{(k)}$ be the k -step estimator defined in (10) and $\hat{\theta}_n^{(0)}$ be n^ψ -consistent for $0 < \psi \leq 1/2$. Define $\|\hat{\theta}_n^{(k)} - \hat{\theta}_n\| = O_P(n^{-r_k})$. We show that r_k increases from ψ to $(r + 1/4)$ as $k \rightarrow \infty$. Specifically, we have

$$(15) \quad \|\hat{\theta}_n^{(k)} - \hat{\theta}_n\| = O_P(n^{-S(\psi, r, k)}).$$

This implies that

$$(16) \quad \|\widehat{\theta}_n^{(k^*)} - \widehat{\theta}_n\| = o_P(n^{-1/2}),$$

where $k^* = K_1(\psi, r) + \widetilde{\text{int}}[\log((2r - \widetilde{S}_1(\psi, r))/(2r - 1/2))/\log 2]$.

Interestingly, we notice that the optimal bound of $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\|$, i.e. $O_P(n^{-r-1/4})$, is intrinsically determined by how accurately we estimate the nuisance parameter, i.e., the value of r . This bound can not be further improved unless we are willing to make stronger assumptions than M1-M4, which seem unrealistic. From the form of $S(\psi, r, k)$, we find that more accurate initial estimate leads to higher order asymptotic efficiency of $\widehat{\theta}_n^{(k)}$. How to obtain $\widehat{\theta}_n^{(0)}$ with proper convergence rate will be discussed in Section 5.

REMARK 1. *Some simple analysis of $S(\psi, r, k)$ reveals that (i) $k^* = 1$ if $\widehat{\theta}_n^{(0)}$ is \sqrt{n} consistent, i.e., $\psi = 1/2$; (ii) $k^* = 2$ if $r \leq \psi < 1/2$.*

REMARK 2. *We briefly discuss the choice of step sizes in the proof of Theorem 1. Denote the convergence rate of $\|\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n\|$ as $O_P(n^{-r_{k-1}})$. According to the Proof of Theorem 1, the convergence rate of $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\|$ is improved through the below three stages: (i) $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\| = O_P(\|\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n\|^{3/2})$ when $r_{k-1} < r$ and we choose $(s_n, t_n) \asymp (n^{-3r_{k-1}/2}, n^{-r_{k-1}/2})$; (ii) $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\| = O_P(\|\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n\|^{1/2}n^{-r})$ when $r \leq r_{k-1} < 1/2$ and we choose $(s_n, t_n) \asymp (n^{-r-r_{k-1}/2}, n^{-r_{k-1}/2})$; (iii) $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\| = O_P(n^{-r-1/4})$ when $r_{k-1} \geq 1/2$ and we choose $(s_n, t_n) \asymp (n^{-r-1/4}, n^{-r_{k-1}/2})$.*

We apply Theorem 1 to the following two examples whose detailed technical illustrations and model assumptions can be found in [31, 34]. The required Conditions in Theorem 1 are verified in [13, 14] for Examples 1-2.

We can also apply our theory to the semiparametric regression under shape constraints, e.g., semiparametric additive isotonic regression [11].

Example 1: Cox Model under Current Status Data

In the Cox proportional hazards model, the hazard function of the survival time T of a subject with covariate Z is expressed as:

$$\lambda(t|z) \equiv \lim_{\Delta \rightarrow 0} \frac{1}{\Delta} \Pr(t \leq T < t + \Delta | T \geq t, Z = z) = \lambda(t) \exp(\theta' z),$$

where λ is an unspecified baseline hazard function. We consider the current status data where each subject is observed at a single examination time Y to determine if an event has occurred, but the event time T cannot be known exactly. Specifically, the observed data are n realizations of $X = (Y, \delta, Z) \in \mathbb{R}^+ \times \{0, 1\} \times \mathbb{R}$, where $\delta = I\{T \leq Y\}$. The cumulative hazard function $\eta(y) = \int_0^y \lambda(t) dt$ is considered as the nuisance parameter. The parameter space \mathcal{H} for η is restricted to a set of nondecreasing and cadlag functions on some compact interval. In this model, it is well known that both $\hat{\eta}(\theta)$ and $\log pl_n(\theta)$ have no explicit forms, and can only be calculated numerically via the iterative convex minorant algorithm, see [24]. As for the convergence rate of η , Murphy and van der Vaart (1999) showed $\|\hat{\eta}(\tilde{\theta}_n) - \eta_0\|_2 = O_P(\|\tilde{\theta}_n - \theta_0\| \vee n^{-1/3})$, where $\|\cdot\|_2$ is the L_2 norm. According to Theorem 1, we establish the following table to depict the convergence of $\hat{\theta}_n^{(k)}$ to $\hat{\theta}_n$ given different initial estimates until it reaches the lower bound $O_P(n^{-7/12})$.

Table 1. *Cox Model under Current Status Data* ($r = 1/3$)

	$\psi = 1/2$	$\psi = 1/3$	$\psi = 1/4$
Cox	$r_1 = 7/12$	$r_1 = 1/2, r_2 = 7/12$	$r_1 = 3/8, r_2 = 25/48, r_3 = 7/12$
Models	$k^* = 1$	$k^* = 2$	$k^* = 2$

Remark: Define $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\| = O_P(n^{-r_k})$.

Example 2: Semiparametric Mixture Model in Case-Control Studies

Roeder, Carroll and Lindsay (1996) consider the logistic regression model with a missing covariate for case-control studies. In this model, they observe two independent random samples: one complete component $Y_C = (D_C, W_C)$ and Z_C of the size n_C , and one reduced component $Y_R = (D_R, W_R)$ of the size n_R . Following the assumptions given in [34], the likelihood for $x = (y_C, y_R, z_C)$ is defined as

$$lik(\theta', \eta)(x) = p_{\theta'}(y_C | z_C) \eta\{z_C\} \int p_{\theta'}(y_R | z) d\eta(z),$$

where $d\eta$ denotes the density of η w.r.t. some dominating measure, and

$$p_{\theta'}(y|z) = \left(\frac{\exp(\gamma + \theta e^z)}{1 + \exp(\gamma + \theta e^z)} \right)^d \left(\frac{1}{1 + \exp(\gamma + \theta e^z)} \right)^{1-d} \frac{1}{\sigma} \phi \left(\frac{w - \alpha_0 - \alpha_1 z}{\sigma} \right),$$

where $\phi(\cdot)$ denotes the standard normal density. The unknown parameters are $\theta' = (\theta, \alpha_0, \alpha_1, \gamma, \sigma)$ ranging over the compact $\Theta' \subset \mathbb{R}^4 \times (0, \infty)$ and the distribution η of the regression variable restricted to the set of nondegenerate probability distributions with a known compact support. In this semiparametric mixture model, we will concentrate on the regression coefficient θ , considering $\theta_2 = (\alpha_0, \alpha_1, \gamma, \sigma)$ and η as nuisance parameters. The NPMLE $\widehat{\eta}(\theta)(z)$ is a weighted average of two empirical distributions and the

log-profile likelihood implicitly defined as

$$\widehat{S}_n(\theta) = \log pl_n(\theta) = \sup_{\theta_2, \eta} \log lik_n(\theta', \eta)$$

has no explicit form. Let $(\widehat{\theta}_{2,\theta}, \widehat{\eta}(\theta))$ be the profile likelihood estimator for (θ_2, η) so that $\widehat{\theta}'_\theta = (\theta, \widehat{\theta}_{2,\theta})$. Both $\widehat{\eta}(\theta)(z)$ and $\widehat{S}_n(\theta)$ can be computed efficiently via the iterative algorithm in Section 4 of [34], a special case of our general algorithm. Murphy and van der Vaart (1999) showed that, for any $\widetilde{\theta}_n \xrightarrow{P} \theta_0$,

$$(17) \quad \|\widehat{\eta}(\widetilde{\theta}_n) - \eta_0\|_{BL_1} + \|\widehat{\theta}'_{\widetilde{\theta}_n} - \theta'_0\| = O_P(|\widetilde{\theta}_n - \theta_0| \vee n^{-\frac{1}{2}}),$$

where $\|\cdot\|_{BL_1}$ is the weak topology. This implies that $r = 1/2$. The following Table 2 is similar as Table 1. Interestingly, we find that $\widehat{\theta}_n^{(k)}$ converges to $\widehat{\theta}_n$ at a faster rate in the second model by comparing Tables 1 and 2.

Table 2. *Semiparametric Mixture Model in Case-Control Studies* ($r = 1/2$)

	$\psi = 1/2$	$\psi = 1/3$	$\psi = 1/4$
Mixture	$r_1 = 3/4$	$r_1 = 1/2, r_2 = 3/4$	$r_1 = 3/8, r_2 = 9/16, r_3 = 3/4$
Models	$k^* = 1$	$k^* = 2$	$k^* = 2$

Remark: Define $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\| = O_P(n^{-r_k})$.

4. Semiparametric Estimation under Regularization. In this section, we consider the semiparametric estimation under two types of regularizations, i.e., kernel estimation and penalized estimation. In contrast with the profile likelihood estimation, the regularized $\widehat{S}_n(\theta)$ is usually differentiable although its form may vary under different regularizations. We first

present a unified framework for studying $\hat{\theta}_n^{(k)}$ when $\hat{S}_n(\theta)$ is third order differentiable, and then present several examples corresponding to different regularizations which fit into this framework. We also discuss the variable selection in partly linear models as an extension of the penalized estimation.

In this section, we construct $\hat{\theta}_n^{(k)}$ in step (III) as follows:

$$(18) \quad \hat{\theta}_n^{(k)} = \hat{\theta}_n^{(k-1)} + \left[\hat{I}_n(\hat{\theta}_n^{(k-1)}) \right]^{-1} \hat{\ell}_n(\hat{\theta}_n^{(k-1)}),$$

where $\hat{\ell}_n(\cdot) = \hat{S}_n^{(1)}(\cdot)/n$ and

$$(19) \quad \hat{I}_n(\cdot) = -\hat{S}_n^{(2)}(\cdot)/n,$$

where $\hat{S}_n^{(j)}(\cdot)$ is the j -th derivative of $\hat{S}_n(\cdot)$. When $\hat{S}_n^{(2)}(\theta)$ has no explicit form or is hard to compute, we may prefer constructing $[\hat{I}_n(\theta)]_{ij}$ as

$$(20) \quad -n^{-1/2} \frac{[\hat{S}_n^{(1)}(\theta + n^{-1/2}t_2v_j)]_i - [\hat{S}_n^{(1)}(\theta + n^{-1/2}t_1v_j)]_i}{t_2 - t_1},$$

where t_1 and t_2 ($t_1 < t_2$) are arbitrarily fixed real numbers.

Recall that

$$S_n(\theta) = n\mathbb{P}_n \log \text{lik}(\theta, \eta(\theta))$$

and define $S_n^{(j)}(\cdot)$ as the j -th derivative of $S_n(\cdot)$. In view of the discussions in Section 2, i.e. (5) & (8), we expect that $\hat{\theta}_n^{(k)}$ converges to $\hat{\theta}_n$ if $\hat{S}_n^{(j)}(\cdot)$ approximates $S_n^{(j)}(\cdot)$ well enough round θ_0 for $j = 1, 2, 3$. Therefore, we assume the following general condition G.

G. Assume that

$$(21) \quad \frac{1}{n} \hat{S}_n^{(1)}(\theta_0) - \frac{1}{n} S_n^{(1)}(\theta_0) = O_P(n^{-2g}),$$

$$(22) \quad \sup_{\theta \in \mathcal{N}(\theta_0)} \left| \frac{1}{n} \hat{S}_n^{(2)}(\theta) - \frac{1}{n} S_n^{(2)}(\theta) \right| = O_P(n^{-g}),$$

$$(23) \quad \sup_{\theta \in \mathcal{N}(\theta_0)} \left| \frac{1}{n} \hat{S}_n^{(3)}(\theta) \right| = O_P(1),$$

where $1/4 < g \leq 1/2$.

We will provide two sets of sufficient conditions for G in the kernel estimation, where the value of g is determined by the bandwidth order, and in the penalized estimation, where the value of g is determined by the smoothing parameter, respectively. In this sense, we can think g is a measure of the convergence rate of $\hat{\eta}(\theta)$ as in (13). We may verify (23) by showing

$$(24) \quad \sup_{\theta \in \mathcal{N}(\theta_0)} \left| \frac{1}{n} \hat{S}_n^{(3)}(\theta) - \frac{1}{n} S_n^{(3)}(\theta) \right| = o_P(1),$$

and that the class of functions $\{(\partial^3/\partial\theta^3) \log \text{lik}(x; \theta, \eta(\theta)) : \theta \in \mathcal{N}(\theta_0)\}$ is P-Glivenko-Cantelli and that

$$\sup_{\theta \in \mathcal{N}(\theta_0)} E |(\partial^3/\partial\theta^3) \log \text{lik}(X; \theta, \eta(\theta))| < \infty.$$

Define

$$(25) \quad R(\psi, g, k) = \begin{cases} R_1(\psi, g, k) & k \leq L_1(\psi, g) \\ R_2(R_1(\psi, g, L_1(\psi, g)), g, k - L_1(\psi, g)) & k > L_1(\psi, g) \end{cases}$$

where

$$\begin{aligned} R_1(\psi, g, k) &= (1/2 - g) + 2^k(\psi + g - 1/2), \\ L_1(\psi, g) &= \text{int} \left[\frac{\log(g/(g + \psi - 1/2))}{\log 2} \right], \\ \tilde{L}_1(\psi, g) &= \widetilde{\text{int}} \left[\frac{\log(g/(g + \psi - 1/2))}{\log 2} \right], \\ R_2(\psi, g, k) &= kg + \psi. \end{aligned}$$

THEOREM 2. *Suppose that Condition G holds. If $\hat{\theta}_n$ defined in (9) is consistent and \tilde{I}_0 is nonsingular, then we have*

$$(26) \quad \begin{aligned} \sqrt{n}(\hat{\theta}_n - \theta_0) &= \frac{1}{\sqrt{n}} \sum_{i=1}^n \tilde{I}_0^{-1} \tilde{\ell}_0(X_i) + O_P(n^{1/2-2g}) \\ &\xrightarrow{d} N(0, \tilde{I}_0^{-1}). \end{aligned}$$

Let $\widehat{\theta}_n^{(k)}$ be the k -step estimator defined in (18) and $\widehat{\theta}_n^{(0)}$ be n^ψ -consistent for $(1/2 - g) < \psi \leq 1/2$. Define $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\| = O_P(n^{-r_k})$. We show that r_k increases from ψ to ∞ as $k \rightarrow \infty$. Specifically, we show

$$(27) \quad \|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\| = O_P(n^{-2^k \psi}) \quad \text{if } \widehat{I}_n(\cdot) \text{ is defined in (19),}$$

$$(28) \quad \|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\| = O_P(n^{-R(\psi, g, k)}) \quad \text{if } \widehat{I}_n(\cdot) \text{ is defined in (20).}$$

This implies that

$$\|\widehat{\theta}_n^{(k^*)} - \widehat{\theta}_n\| = o_P(n^{-1/2}),$$

where $k^* = \widetilde{\text{int}}[\log(1/2\psi)/\log 2]$ for (27) and $k^* = \widetilde{L}_1(\psi, g)$ for (28).

Note that (27) is a statistical counterpart to the well known quadratic convergence of the Newton Ralphson algorithm; see Page 312 of [32]. Based on Theorems 1 and 2, we conclude that (i) more than k^* iterations, i.e., k , will not change the limiting distribution of $\widehat{\theta}_n^{(k)}$, but will improve its higher order asymptotic efficiency; (ii) the higher order asymptotic efficiency of $\widehat{\theta}_n^{(k)}$ is determined by how accurately η is estimated, i.e., the values of r and g ; (iii) $\widehat{\theta}_n^{(k)}$ converges to $\widehat{\theta}_n$ faster when \widehat{I}_n is constructed as an analytical derivative no matter whether the regularization is used or not.

REMARK 3. Given that the initial estimate is \sqrt{n} consistent, we have

$$\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\| = O_P(n^{-2^{k-1}}) \quad \text{if } \widehat{I}_n(\cdot) \text{ is constructed as in (19),}$$

$$\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\| = O_P(n^{-(1/2+kg)}) \quad \text{if } \widehat{I}_n(\cdot) \text{ is constructed as in (20)}$$

based on Theorem 2. This implies $k^* = 1$.

A useful application of Theorem 2 is to the parametric models, i.e., η is known. In this case, $\widehat{S}_n(\theta)$ becomes $\ell_\theta(X) = \log \text{lik}(\theta; X)$, and we simplify

the general Condition G to the following Conditions P1-P2. Denote the first, second and third derivative of $\ell_\theta(\cdot)$ w.r.t. θ as $\dot{\ell}_\theta(\cdot)$, $\ddot{\ell}_\theta(\cdot)$ and $\ell_\theta^{(3)}(\cdot)$, respectively. The information matrix at θ_0 is defined as I_0 .

P1. $\dot{\ell}_\theta(\cdot)$ and $\ddot{\ell}_\theta(\cdot)$ are absolutely continuous in θ .

P2. There exists a $\delta > 0$ such that, for any $|t| \leq \delta$,

$$(29) \quad E \left[\ell_{\theta_0+t}^{(i+1)}(X_1) \right]^2 \leq K_i \quad \text{for some finite constant } K_i,$$

where $i = 1, 2$.

We can easily prove Corollary 1 by following similar analysis in Theorem 2 and considering Lemma A.4. Thus, its proof is skipped.

COROLLARY 1. *Suppose that Conditions P1 & P2 hold. If the parametric MLE $\hat{\theta}_n$ is consistent and I_0 is nonsingular, then we have*

$$(30) \quad \sqrt{n}(\hat{\theta}_n - \theta_0) = \frac{1}{\sqrt{n}} \sum_{i=1}^n I_0^{-1} \dot{\ell}_{\theta_0}(X_i) + O_P(n^{-1/2}).$$

Let $\hat{\theta}_n^{(k)}$ be the k -step estimator defined in (18) and $\hat{\theta}_n^{(0)}$ be n^ψ -consistent for $0 < \psi \leq 1/2$. Define $\|\hat{\theta}_n^{(k)} - \hat{\theta}_n\| = O_P(n^{-r_k})$. We show that r_k increases from ψ to ∞ as $k \rightarrow \infty$. Specifically, we show

$$(31) \quad \|\hat{\theta}_n^{(k)} - \hat{\theta}_n\| = O_P(n^{-2^k \psi}) \quad \text{if } \hat{I}_n(\cdot) \text{ is defined in (19),}$$

$$(32) \quad \|\hat{\theta}_n^{(k)} - \hat{\theta}_n\| = O_P(n^{-R(\psi, 1/2, k)}) \quad \text{if } \hat{I}_n(\cdot) \text{ is defined in (20).}$$

The above Corollary generalizes the one/two-step estimation results in parametric models, i.e., [25]. Comparing Theorem 2 with Corollary 1, we notice that $\hat{\theta}_n^{(k)}$ converges to $\hat{\theta}_n$ at a slower rate in semiparametric models. This results from the presence of an infinite dimensional η estimated at a slower-than-parametric rate, see Lemmas A.3 and A.4.

REMARK 4. *We would like to mention that the regularized $\widehat{S}_n(\theta)$ may be in-differentiable in some semiparametric models, e.g., the penalized estimation of partly linear models under current status data studied in [15]. In such cases, we can take the discretization approach to construct $\widehat{\theta}_n^{(k)}$ as in the profile likelihood framework, i.e., (10), and obtain similar results as in Theorem 1 if we can prove that the non-smooth $\widehat{S}_n(\theta)$ share the same higher order quadratic expansion as $\log pl_n(\theta)$. Indeed, Cheng and Kosorok (2009) have proven such results for the non-smooth regularized $\widehat{S}_n(\theta)$ under weaker conditions. See [10] for more elaborations.*

REMARK 5. *We want to point out that our construction of the semi-parametric efficient estimate in Sections 3 and 4 does not require knowing the form of the efficient score function or apply the sample splitting techniques [5] and the drop-one-out tricks [21]. Therefore, our approach is different from the classical construction in the semiparametric literature, i.e., [5, 21], and applies to more general class of semiparametric models.*

4.1. *Kernel Estimation in Semiparametric Models.* In this subsection, we consider the kernel estimation in semiparametric models. Due to its simple form, the kernel estimate of η and the related iterative algorithm of estimating θ are widely used in semiparametric models, e.g., [2, 40]. In particular, the kernel approach is proven to be a powerful inferential tool for the class of conditionally parametric models (CPM), see [36, 37]. Thus, in this subsection, we will focus on the class of CPM although our conclusions can be extended to more general class of semiparametric models by incorporating the results in [2]. Under kernel estimation, k^* is shown to depend

on the order of bandwidth used in the kernel function.

The class of CPM was first introduced by Severini and Wong (1992) and further generalized to the quasi-likelihood framework by Severini and Staniswalis (1994). Specifically, we observe $X = (Y, W, Z)$ such that the distribution of Y conditional on partitioned covariates $W = w$ and $Z = z$ is parameterized by a finite dimensional parameter $\phi = (\theta, \lambda_z)$, where $\lambda_z \in H \subset \mathbb{R}$ depends on the value of z as a function $\eta(z)$. The joint distribution of (W, Z) is assumed to be independent of ϕ . Thus, this semiparametric model has the log-likelihood $\log \text{lik}(X; \theta, \eta(z))$ and is called conditionally parametric. The practical performance of the iterative estimation procedure (I)-(IV) for the CPM is extensively studied in [37].

We assume that $\eta(z) \in \mathcal{H} = \{h \in C^2(\mathcal{Z}) : h(z) \in \text{interior}(H) \text{ for all } z \in \mathcal{Z}\}$. An important feature of CPM is that its least favorable curve can be expressed as (see [36] for details)

$$(33) \quad \eta(\theta)(z) = \arg \sup_{\eta \in C^2[0,1]} E[\log \text{lik}(X; \theta, \eta) | Z = z],$$

and thus its kernel estimate is written as

$$(34) \quad \hat{\eta}(\theta)(z) = \arg \sup_{\eta \in C^2[0,1]} \sum_{i=1}^n \log \text{lik}(X_i; \theta, \eta(Z_i)) K\left(\frac{z - Z_i}{b_n}\right),$$

where $K(\cdot)$ is a kernel with the bandwidth $b_n \rightarrow 0$. For example, if $(Y|w = W, Z = z) \sim N(\theta'w, \eta(z))$, then we have

$$(35) \quad \begin{aligned} \hat{\eta}(\theta)(z) &= \frac{\sum_{i=1}^n (Y_i - \theta'W_i)^2 K((z - Z_i)/b_n)}{\sum_{i=1}^n K((z - Z_i)/b_n)}, \\ \hat{S}_n(\theta) &= -\frac{1}{2} \sum_{i=1}^n \frac{(Y_i - \theta'W_i)}{\hat{\eta}(\theta)(Z_i)} - \frac{1}{2} \sum_{i=1}^n \log \hat{\eta}(\theta)(Z_i). \end{aligned}$$

Although $\hat{\eta}(\theta)$ (and thus $\hat{S}_n(\theta)$) solved from (34) generally has no explicit

form, based on (34) we can control the asymptotic behaviors of $\hat{\eta}(\theta)$ (and thus $\hat{S}_n(\theta)$) by assuming proper kernel conditions, see the below Example 3.

By exploiting the parametric structure of CPM, we will show that $\hat{S}_n(\theta)$ satisfies the general Condition G under the below regularity conditions K1-K2 and convergence rate conditions C1-C2.

K1. For arbitrary $\theta_1 \in \Theta$ and $\lambda_1 \in H$, if $\theta \neq \theta_1$, then $E_{\theta_1, \lambda_1} \log \text{lik}(X; \theta, \lambda) < E_{\theta_1, \lambda_1} \log \text{lik}(X; \theta_1, \lambda_1)$;

K2. Assume that

$$(36) \quad E \left\{ \sup_{(\theta, \lambda) \in \Theta \times H} \left| \frac{\partial^{r+s} \log \text{lik}(X; \theta, \lambda)}{\partial \theta^r \partial \lambda^s} \right|^2 \right\} < \infty$$

for all $r, s = 0, \dots, 4$ and $r + s \leq 4$.

The above identifiability condition K1 and smoothness condition K2 are also used in [36]. Our next conditions C1-C2 are concerned about the smoothness and convergence rate of $\eta(\theta)$ and $\hat{\eta}(\theta)$. In the below, we denote the derivative of $\eta(\theta)$ ($\hat{\eta}(\theta)$) w.r.t. θ as $\eta^{(s)}(\theta)$ ($\hat{\eta}^{(s)}(\theta)$), and their values at θ_0 as $\eta_0^{(s)}$ ($\hat{\eta}_0^{(s)}$).

C1. Assume that, for all $r, s = 0, 1, 2, 3$ and $r + s \leq 3$,

$$\frac{\partial^{r+s}}{\partial z^r \partial \theta^s} \eta(\theta)(z) \quad \text{and} \quad \frac{\partial^{r+s}}{\partial z^r \partial \theta^s} \hat{\eta}(\theta)(z)$$

exist and $\sup_{\theta \in \mathcal{N}(\theta_0)} \|\eta^{(s)}(\theta)\|_\infty < \infty$.

C2. Assume that

$$(37) \quad \sup_{\theta \in \mathcal{N}(\theta_0)} \|\hat{\eta}^{(s)}(\theta) - \eta^{(s)}(\theta)\|_\infty = O_P(n^{-g}) \quad \text{for } s = 0, 1, 2,$$

$$(38) \quad \sup_{\theta \in \mathcal{N}(\theta_0)} \|\hat{\eta}^{(3)}(\theta) - \eta^{(3)}(\theta)\|_\infty = o_P(1),$$

$$(39) \quad \left\| \frac{\partial}{\partial z} \hat{\eta}_0(z) - \frac{\partial}{\partial z} \eta_0(z) \right\|_\infty = o_P(n^{-\delta}),$$

$$(40) \quad \left\| \frac{\partial}{\partial z} \hat{\eta}_0^{(1)}(z) - \frac{\partial}{\partial z} \eta_0^{(1)}(z) \right\|_\infty = o_P(n^{-\delta}).$$

for some $g \in (1/4, 1/2]$ and $(2g - 1/2) \leq \delta \leq g$.

In view of (33)-(34), we can verify C2 by applying the kernel theories under some proper kernel conditions and K1-K2. For example, in Lemma 1, we show that the convergence rate of the kernel estimate in (37), which determines the value of g in (21)-(22), relies on the order of bandwidth b_n used in (34). Note that our convergence rate condition C2 also satisfies (13) assumed for the NPMLE since

$$\begin{aligned} \|\hat{\eta}(\tilde{\theta}_n) - \eta_0\| &\leq \|\hat{\eta}(\tilde{\theta}_n) - \hat{\eta}(\theta_0)\|_\infty + \|\hat{\eta}(\theta_0) - \eta(\theta_0)\|_\infty \\ &\leq O_P(\|\tilde{\theta}_n - \theta_0\| \vee n^{-g}) \end{aligned}$$

by the construction that $\eta(\theta_0) = \eta_0$, C1-C2 and (37). Our conditions K1-K2 and C1-C2 are generally stronger than M1-M4 and (13) since the semiparametric models under consideration have the assumed parametric structure.

THEOREM 3. *Assuming that Conditions K1-K2 and C1-C2 hold, then the Condition G required in Theorem 2 is satisfied for the kernel estimation in conditionally parametric models.*

The consistency of $\hat{\theta}_n$ required in Theorem 2 can be established if we further require the global condition $\sup_{\theta \in \Theta} \|\hat{\eta}(\theta) - \eta(\theta)\|_\infty \rightarrow 0$, see Proposition 1 of [36]. In the next example, we apply Theorems 2 and 3 to a subclass of CPM, called conditionally exponential models (CEM), in which $\hat{\eta}(\theta)$ has a closed-form. This makes the verifications of C1-C2 much easier. The relation between k^* and the order of b_n in (34) is also specified in the below example. We may also apply our theories to the more complicated semiparametric transformation model, i.e., [27].

Example 3. Conditionally Exponential Models

In CEM, there exists a function $\psi_\theta(\cdot)$ such that the conditional distribution of $\psi_\theta(Y, W)$ given $Z = z$ does not depend on θ and forms an exponential family. And its log-likelihood can be expressed as

$$\log \text{lik}(X; \theta, \eta) = \psi_\theta(Y, W)T(\eta(Z)) - A(\eta(Z)) + S(\psi_\theta(Y, W))$$

for some functions T , A and S . Some simple algebra gives that

$$(41) \quad \hat{\eta}(\theta)(z) = \rho \left(\frac{\sum_{i=1}^n \psi_\theta(Y_i, W_i) K((z - Z_i)/b_n)}{\sum_{i=1}^n K((z - Z_i)/b_n)} \right),$$

where $\eta = \rho\{E_{\theta, \eta}(\psi_\theta(Y, W))\}$. In the previous conditional normal model, we have $\psi_\theta(Y, W) = (Y - \theta'W)^2$ and $\rho(t) = t$. Another example is that $(Y|W = w, Z = z) \sim \text{Exp}(0, \exp(\theta'w + \eta(z)))$ in which $\psi_\theta(Y, W) = Y \exp(-\theta'W)$ and $\rho(t) = \log t$.

It is easy to verify that Conditions K1-K2 are satisfied for the above conditional normal and exponential models if $\Theta \times H$ is assumed to be a compact subset of \mathbb{R}^2 . We will verify Conditions C1-C2 by the use of the following Lemma. Let $\psi_\theta^{(j)}(\cdot)$ be $(\partial^j/\partial\theta^j)\psi_\theta(\cdot)$ and $f_{\theta j}(\cdot|z)$ be its conditional density. Denote $f(z)$ as the marginal density of Z . Let M be a compact set such that $m_\theta(z) \equiv E[\psi_\theta(Y, W)|Z = z] \in \text{interior}(M)$ for all z, θ .

LEMMA 1. *Assume the following conditions hold:*

- (a) $E\{\sup_\theta |\psi_\theta^{(j)}|\} < \infty$ for $j = 0, 1, 2, 3$;
- (b) For some even integer $q \geq 10$, $\sup_\theta E\{|\psi_\theta^{(j)}|^q\} < \infty$ for $j = 0, 1, 2, 3$;
- (c) $\sup_\theta \sup_x |f_{\theta j}^{(r)}(y, w|z)| < \infty$ for $j = 0, 1, 2$ and $r = 0, \dots, 4$;
- (d) $\sup_z |f^{(r)}(z)| < \infty$ for $r = 0, \dots, 4$;
- (e) $0 < \inf_z f(z) \leq \sup_z f(z) < \infty$;

$$(f) \sup_{m \in M} |\rho^{(j)}(m)| < \infty \text{ for } j = 0, \dots, 4.$$

Suppose that the kernel function $K(\cdot)$ satisfies

$$\begin{aligned} \int K(u)du &= 1, \quad \int uK(u)du = 0, \quad \int u^2K(u)du < \infty, \\ \sup_u |K^{(r)}(u)| &< \infty \text{ for } r = 0, \dots, 4. \end{aligned}$$

If we choose $b_n \asymp n^{-\alpha}$ for $1/8 < \alpha < (q-2)/(4q+16)$, then Condition C2 is satisfied with

$$(42) \quad g = 2\alpha \wedge \left(\frac{q}{2q+4} - \frac{\alpha(q+4)}{q+2} - \epsilon \right),$$

$$(43) \quad \delta = \frac{q}{2q+4} - \frac{\alpha(2q+6)}{q+2} - 2\epsilon$$

for any $\epsilon > 0$.

The above Lemma specifies the relation between the bandwidth order α in the kernel estimation (41) and k^* in Theorem 2. By some algebra, we can verify that $g \in (1/4, 1/2]$ and $(2g - 1/2) \leq \delta \leq g$ given the above range of α and q . We want to point out that the convergence rates of $\hat{\eta}(\theta)$ (and its derivatives) may be improved, i.e., larger value of g , under more restrictive kernel conditions, see [2, 39].

We next apply Theorems 2-3 and Lemma 1 to the previous conditional normal (exponential) examples, in which q is shown to be arbitrarily large and M is chosen as a sufficiently large compact subset of $(0, \infty)$. For simplicity, in the below table, we assume that $q = 28$, $b_n \asymp n^{-1/5}$, $\epsilon = 1/600$ such that $g = 151/600 > 1/4$ and $\delta = 1/20$ according to (42)-(43).

Table 3. *Conditional Normal (Exponential) Model* ($g = 151/600$)

	$\psi = 1/2$	$\psi = 1/3$
Construction I	$r_1 = 1$ $k^* = 1$	$r_1 = 2/3$ $k^* = 1$
Construction II	$r_1 = 451/600$ $k^* = 1$	$r_1 = 251/600, r_1 = 353/600$ $k^* = 2$
<hr/>		
	$\psi = 1/4$	
Construction I	$r_1 = 1/2, r_2 = 1$ $k^* = 2$	
Construction II	$r_1 = 151/600, r_2 = 153/600, r_3 = 157/600, r_4 = 165/600$ $r_5 = 181/600, r_6 = 213/600, r_7 = 277/600, r_8 = 405/600$ $k^* = 8$	

Remark: ψ : convergence rate for $\widehat{\theta}_n^{(0)}$; r_k : Define $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\| = O_P(n^{-r_k})$; Construction I: \widehat{I}_n is constructed by (19); Construction II: \widehat{I}_n is constructed by (20).

4.2. Penalized Estimation in Semiparametric Models. In many semiparametric models involving a smooth nuisance parameter, it is often convenient and beneficial to perform estimation using penalization, e.g., [28, 38]. Under regularity conditions, penalized semiparametric log-likelihood estimation can yield fully efficient estimates for θ , see (50). In penalized estimation framework, the value of k^* is shown to relate to the order of the smoothing parameter λ_n . A surprising result we have is that k^* iterations are sufficient for achieving the estimation efficiency and recovering the sparsity simultaneously in high dimensional data, see the below partly linear example.

In this subsection, we assume that η belongs to the Sobolev class of

functions $\mathcal{H}_k \equiv \{\eta : J^2(\eta) = \int_{\mathcal{Z}} (\eta^{(k)}(z))^2 dz < \infty\}$, where $\eta^{(j)}$ is the j -th derivative of η and \mathcal{Z} is some compact set on the real line. The penalized log-likelihood in this context is defined as

$$(44) \quad \log \text{lik}_{\lambda_n}(\theta, \eta) = n\mathbb{P}_n \log \text{lik}(\theta, \eta) - n\lambda_n^2 J^2(\eta),$$

where λ_n is a smoothing parameter. We assume the following bounds for λ_n :

$$(45) \quad \lambda_n = o_P(n^{-1/4}) \quad \text{and} \quad \lambda_n^{-1} = O_P(n^{k/(2k+1)}).$$

In practice, λ_n can be obtained by cross-validation [42]. Here, the regularized $\widehat{S}_n(\theta)$ becomes the log-profile penalized likelihood $\widehat{S}_{\lambda_n}(\theta)$:

$$(46) \quad \widehat{S}_{\lambda_n}(\theta) = \log_{\lambda_n}(\theta, \widehat{\eta}_{\lambda_n}(\theta)),$$

where $\widehat{\eta}_{\lambda_n}(\theta) = \arg \sup_{\eta \in \mathcal{H}_k} \log \text{lik}_{\lambda_n}(\theta, \eta)$ for any fixed θ and λ_n . We define the penalized estimate as $\widehat{\theta}_{\lambda_n}$.

The construction of the k -step penalized estimate $\widehat{\theta}_{\lambda_n}^{(k)}$ follows from (18) just with the change of $\widehat{S}_n(\cdot)$ to $\widehat{S}_{\lambda_n}(\cdot)$. For the penalized estimation, we need to slightly modify Condition G as follows:

G'. Assume that, for some constant c ,

$$(47) \quad \frac{1}{n} \widehat{S}_{\lambda_n}^{(1)}(\theta_0) - c\mathbb{P}_n \widetilde{\ell}_0 = O_P(\lambda_n^2),$$

$$(48) \quad \sup_{\theta \in \mathcal{N}(\theta_0)} \left| \frac{1}{n} \widehat{S}_{\lambda_n}^{(2)}(\theta) + c\widetilde{I}_0 \right| = O_P(\lambda_n \vee \|\theta - \theta_0\|),$$

$$(49) \quad \sup_{\theta \in \mathcal{N}(\theta_0)} \left| \frac{1}{n} \widehat{S}_{\lambda_n}^{(3)}(\theta) \right| = O_P(1).$$

It is easy to verify Condition G' if $\widehat{\eta}_{\lambda_n}(\theta)$ has an explicit expression and $\log \text{lik}_{\lambda_n}(\theta, \eta)$ is smooth w.r.t. (θ, η) , see the below example 4. We also want to point out that Condition G' is relaxable to a large extent, see Remark 4.

For example, rather than the explicit form of $\hat{\eta}_{\lambda_n}$, we may only require $\hat{\eta}_{\lambda_n}$ satisfying $\|\hat{\eta}_{\lambda_n}(\tilde{\theta}_n) - \eta_0\| = O_P(\|\tilde{\theta}_n - \theta_0\| \vee \lambda_n)$ for any consistent $\tilde{\theta}_n$.

In view of (5) and (8), we can prove Theorem 4 similarly as Theorem 2.

THEOREM 4. *Suppose Condition G' holds. If the penalized MLE $\hat{\theta}_{\lambda_n}$ is consistent and \tilde{I}_0 is nonsingular, then we have*

$$(50) \quad \sqrt{n}(\hat{\theta}_{\lambda_n} - \theta_0) = \frac{1}{\sqrt{n}} \sum_{i=1}^n \tilde{I}_0^{-1} \tilde{\ell}_0(X_i) + O_P(\sqrt{n}\lambda_n^2).$$

Define $g = \max\{g' : \lambda_n = O_P(n^{-g'})\}$, and thus $1/4 < g \leq k/(2k+1)$ based on Condition (45). Construct $\hat{\theta}_{\lambda_n}^{(k)}$ as in (18) with the change of $\hat{S}_n(\cdot)$ to $\hat{S}_{\lambda_n}(\cdot)$. Then all the conclusions for $\hat{\theta}_n^{(k)}$ in Theorem 2 also hold for $\hat{\theta}_{\lambda_n}^{(k)}$.

The above asymptotic linear expansion (50) was also derived in [15] but under very different conditions. Theorem 4 implies that k^* depends on the order of the smoothing parameter λ_n , i.e., the value of g , see (28). Because of the duality between the penalized estimation and sieve estimation, we expect that the above conclusions also hold for the semiparametric sieve estimation, see [9]. For example, when η_0 is estimated in the form of B-spline (local polynomial) as in [23] ([8, 19]), k^* may rely on the growth rate of the number of basis functions (the order of bandwidth in the kernel function). The detailed theoretical exploration towards this direction is not considered in this article due to the space limitation.

We next apply Theorem 4 to the following partly linear models under high dimensional data. Surprisingly, we discover that one step iteration is sufficient for achieving the semiparametric estimation efficiency and recovering the estimation sparsity simultaneously.

Example 4. Sparse and Efficient Estimation of Partial Spline Model

The partial smoothing spline represents an important class of semiparametric models under penalized estimation. In particular, we consider

$$(51) \quad Y = W'\theta + \eta(Z) + \epsilon,$$

where $\eta \in \mathcal{H}_k$ and $0 \leq Z \leq 1$. For simplicity, we assume that $\epsilon \stackrel{iid}{\sim} N(0, \sigma^2)$ and is independent of W . The normality of ϵ can be relaxed to the sub-exponential tail condition. In this example, we assume that some components of θ_0 are exactly zero which is common for high dimensional data. It is well known that effective variable selection in semiparametric models could greatly improve their prediction accuracy and interpretability, e.g., [7, 16]. To achieve the estimation efficiency and recover sparsity of θ , Cheng and Zhang (2010) proposed the following double penalty estimation approach for (51). Specifically, they define $(\hat{\theta}_{\lambda_n}, \hat{\eta}_{\lambda_n})$ as the minimizer of

$$(52) \quad n\mathbb{P}_n(Y - W'\theta - \eta(Z))^2 + n\lambda_n^2 J^2(\eta) + n\tau_n^2 \sum_{j=1}^d \frac{|\theta_j|}{|\tilde{\theta}_j|^\gamma},$$

where γ is a fixed positive constant and $\tilde{\theta} = (\tilde{\theta}_1, \dots, \tilde{\theta}_d)'$ is the consistent initial estimate, over $\Theta \times \mathcal{H}_k$. We will show that $\hat{\theta}_{\lambda_n}^{(1)}$ possesses the same *semiparametric oracle property*, whose definition is given below, as $\hat{\theta}_{\lambda_n}$.

The standard smoothing spline theory suggests that

$$(53) \quad \hat{\eta}_{\lambda_n}(\theta)(\mathbf{z}) = A(\lambda_n)(\mathbf{y} - \mathbf{w}\theta),$$

where $\hat{\eta}_{\lambda_n}(\theta)(\mathbf{z}) = (\hat{\eta}_{\lambda_n}(\theta)(z_1), \dots, \hat{\eta}_{\lambda_n}(\theta)(z_n))'$, $\mathbf{y} = (y_1, \dots, y_n)'$ and $\mathbf{w} = (w'_1, \dots, w'_n)'$. The expression of the $n \times n$ influence matrix $A(\lambda_n)$ can be found in [22]. Therefore, $\hat{\eta}_{\lambda_n}(\theta)$ is a natural spline of order $(2k - 1)$ with knots on z_i 's for any fixed θ . Plugging (53) back to (52), we have

$$(54) \quad \hat{S}_{\lambda_n}(\theta) = \tilde{S}_{\lambda_n}(\theta) + n\tau_n^2 \sum_{j=1}^d \frac{|\theta_j|}{|\tilde{\theta}_j|^\gamma},$$

where

$$(55) \quad \tilde{S}_{\lambda_n}(\theta) = (\mathbf{y} - \mathbf{w}\theta)'[I - A(\lambda_n)](\mathbf{y} - \mathbf{w}\theta)$$

and I is the identity matrix of size n . When $\tau_n = 0$, the minimizer of (52) becomes the partial smoothing spline, and we denote it as $(\tilde{\theta}_{\lambda_n}, \tilde{\eta}_{\lambda_n})$. Note that $\tilde{\theta}_{\lambda_n}$ has a simple analytic solution form as $\tilde{\theta}_{\lambda_n} = [\mathbf{w}'(I - A(\lambda_n))\mathbf{w}]^{-1}\mathbf{w}'[I - A(\lambda_n)]\mathbf{y}$. However, $\hat{\theta}_{\lambda_n}$ as the minimizer of $\hat{S}_{\lambda_n}(\theta)$ does not have an explicit solution form, and has to be iteratively computed using software like Quadratic Programming or LARS [18], see Section 4 of [16]. Specifically, based on (18)-(19), we construct $\hat{\theta}_{\lambda_n}^{(1)}$ as follows:

$$\hat{\theta}_{\lambda_n}^{(1)} = \hat{\theta}_{\lambda_n}^{(0)} + \left[\frac{\mathbf{w}'(I - A(\lambda_n))\mathbf{w}}{n} \right]^{-1} \left[\frac{\mathbf{w}'(I - A(\lambda_n))(\mathbf{y} - \mathbf{w}\hat{\theta}_{\lambda_n}^{(0)})}{n} - \frac{\tau_n^2}{2}\delta_n(\hat{\theta}_{\lambda_n}^{(0)}) \right],$$

where $\delta_n(\theta) = (\text{sign}(\theta_1)/|\hat{\theta}_1|^\gamma, \dots, \text{sign}(\theta_d)/|\hat{\theta}_d|^\gamma)'$.

Without loss of generality, we write $\theta_0 = (\theta'_1, \theta'_2)'$, where θ_1 consists of all q nonzero components and θ_2 consists of the rest $(d - q)$ zero elements, and define $\hat{\theta}_{\lambda_n} = (\hat{\theta}'_{\lambda_n,1}, \hat{\theta}'_{\lambda_n,2})'$ accordingly. We assume that W has zero mean, strictly positive definite covariance matrix Σ and finite fourth moment. The observations z_i 's (real numbers) are sorted and satisfy

$$(56) \quad \int_0^{z_i} u(w)dw = \frac{i}{n} \quad \text{for } i = 1, 2, \dots, n,$$

where $u(\cdot)$ is a continuous and strictly positive function. The above regularity conditions are commonly used in the literature, e.g., [17, 22], and are relaxable. For example, Condition (56) can be weakened to the case in which z_i 's are sufficiently close to a sequence satisfying (56). For simplicity, we assume that $\gamma = 1$ and $\tilde{\theta}$ is \sqrt{n} -consistent. In this example, $\tilde{\theta}_{\lambda_n}$ or the

difference based estimate [44], which are both known to be \sqrt{n} consistent, can serve as $\tilde{\theta}$ or $\hat{\theta}_{\lambda_n}^{(0)}$.

In this example, we say $\hat{\theta}_{\lambda_n}$ satisfies the *semiparametric oracle property* if

- O1. $\sqrt{n}(\hat{\theta}_{\lambda_n,1} - \theta_1) \xrightarrow{d} N(0, \sigma^2 \Sigma_{11}^{-1})$, where Σ_{11} is the $q \times q$ upper-left submatrix of Σ [Semiparametric Efficiency];
- O2. $\hat{\theta}_{\lambda_n,2} = 0$ with probability tending to one [Sparsity].

Note that $\sigma^2 \Sigma_{11}^{-1}$ in O1 is the semiparametric efficiency bound for θ_1 since z is assumed to be fixed, see [22].

COROLLARY 2. *If $n^{k/(2k+1)}\lambda_n \rightarrow \lambda_0 > 0$ and $n^{k/(2k+1)}\tau_n \rightarrow \tau_0 > 0$, then $\hat{\theta}_{\lambda_n}$ is \sqrt{n} -consistent and satisfies the semiparametric oracle property. Given that $\hat{\theta}_{\lambda_n}^{(0)}$ is \sqrt{n} -consistent, then $\|\hat{\theta}_{\lambda_n}^{(1)} - \hat{\theta}_{\lambda_n}\| = O_P(n^{-1})$ and $\hat{\theta}_{\lambda_n}^{(1)}$ also enjoys the semiparametric oracle property.*

The above Corollary is a simple but interesting application of Theorem 4. We can definitely relax its conditions to the general γ and non- \sqrt{n} consistent $\hat{\theta}_{\lambda_n}^{(0)}$ in which we may require more than one iteration. The conditions on λ_n and τ_n are also chosen for simplicity of expositions and are relaxable. In addition, the proof of Corollary 2 implies the following special case of (50):

$$\sqrt{n}(\hat{\theta}_{\lambda_n,1} - \theta_1) = \frac{1}{\sqrt{n}} \Sigma_{11}^{-1} \sum_{i=1}^n W_{1i} \epsilon_i + O_P\left(n^{-\frac{2k-1}{2(2k+1)}}\right),$$

where W_{1i} is the first q elements of W_i . It is also possible to extend the conclusions of Corollary 2 to the semiparametric quasi-likelihood framework proposed in [28] after more tedious algebra.

5. Initial Estimate. In this paper, we assume the existence of a n^ψ -consistent $\hat{\theta}_n^{(0)}$ just as the numerical result assumes the iterations commence

in a suitable neighborhood of θ_0 . Occasionally, the semiparametric model structure can be exploited to produce a \sqrt{n} -consistent initial estimate, e.g., [35, 44]. However, if such ad-hoc methods are unavailable, a general strategy is to conduct a search of some objective function at finitely many θ -value and call the optimizer as the initial estimate. The numerical analysis literature suggest several search strategies for parametric models, e.g. [20, 41], and Robinson (1988) subsequently proved the consistency and convergence rate of those numerical outcome. In this section, we extend Robinson's results to semiparametric models, i.e., Theorem 5. This extension is nontrivial since our objective function usually has no explicit form and is possibly non-smooth. In fact, our theoretical results on searching $\hat{\theta}_n^{(0)}$ can be applied to any objective functions satisfying the below Conditions I1-I2, and are thus of independent interest.

We use the generalized profile likelihood $\hat{S}_n(\theta)$ as our objective function in semiparametric models. Besides the compactness of Θ and consistency of $\hat{\theta}_n$, we have two primary conditions I1-I2 on $\hat{S}_n(\theta)$ to guarantee the validity of the grid search methods we will consider.

I1. [Asymptotic Uniqueness] For any random sequence $\{\tilde{\theta}_n\} \in \Theta$,

$$(57) \quad [\hat{S}_n(\tilde{\theta}_n) - \hat{S}_n(\hat{\theta}_n)]/n = o_P(1) \text{ implies that } \tilde{\theta}_n - \theta_0 = o_P(1).$$

I2. [Asymptotic Expansion] For any consistent $\tilde{\theta}_n$, \hat{S}_n satisfies

$$(58) \quad \begin{aligned} \hat{S}_n(\tilde{\theta}_n) &= \hat{S}_n(\theta_0) + n(\tilde{\theta}_n - \theta_0)' \mathbb{P}_n \tilde{\ell}_0 - \frac{n}{2} (\tilde{\theta}_n - \theta_0)' \tilde{I}_0 (\tilde{\theta}_n - \theta_0) \\ &\quad + \Delta_n(\tilde{\theta}_n), \end{aligned}$$

where $\Delta_n(\theta) = n\|\theta - \theta_0\|^3 \vee n^{1-2r}\|\theta - \theta_0\|$ and $1/4 < r \leq 1/2$.

Condition I1 is usually implied by the model identifiability conditions. Note that, in Condition I2, we only assume the existence of the asymptotic expansion (58) but not assume the continuity of $\widehat{S}_n(\cdot)$. In Section 3, we have shown that the log-profile likelihood $\log pl_n(\cdot)$ as a special case of $\widehat{S}_n(\cdot)$ satisfies I2 under model Assumptions M1-M4, see (A.5). As for the regularized $\widehat{S}_n(\cdot)$, we can verify I2 under Condition G using a three term Taylor expansion of \widehat{S}_n . Specifically, I2 is satisfied if we assume Conditions K1-K2 & C1-C2 (G') for the kernel estimation (penalized estimation). In particular, we can change n^{1-2r} to $n\lambda_n^2$ in $\Delta_n(\cdot)$ when considering the penalized estimation.

Now we consider two types of grid search: deterministic type and stochastic type. In the former, we form a grid of cubes with sides of length $sn^{-\psi}$ over \mathbb{R}^d for some $s > 0$ and $0 < \psi \leq 1/2$, and thus obtain a set of points $\mathcal{D}_n = \{\theta_{iD}\}$ regularly spaced throughout Θ with cardinality $\text{card}(\mathcal{D}_n) \geq Cn^{d\psi}$ for some $C > 0$. The grid point which maximizes $\widehat{S}_n(\theta)$ is thought of as $\widehat{\theta}_n^{(0)}$. However, this deterministic search could be very slow if the dimension d of θ is high. This motivates us to propose the stochastic search in which the search points are the realizations of some independent random variable $\bar{\theta}$ with strictly positive density around θ_0 , e.g., $\bar{\theta} \sim \text{Unif}[\Theta]$. And we require that the magnitude of the stochastic search points remains n^ψ no matter how large the dimension d is. In theory, the stochastic grid search has significant computational savings over the deterministic alternative. In the below Theorem 5 we rigorously prove that the convergence rates of the above numerical outcomes are n^ψ -consistent for $0 < \psi \leq 1/2$.

THEOREM 5. *Let \mathcal{D}_n be a set of points regularly spaced throughout Θ with $\text{card}(\mathcal{D}_n) \geq Cn^{d\psi}$ for some $C > 0$ and $0 < \psi \leq 1/2$. Assume that $\bar{\theta}$ is*

independent of the data and admits a density having support Θ and bounded away from zero in some neighborhood of θ_0 . Let \mathcal{S}_n be a set of realizations of $\bar{\theta}$ with $\text{card}(\mathcal{S}_n) \geq \tilde{C}n^\psi$ for some $\tilde{C} > 0$ and $0 < \psi \leq 1/2$. Suppose that Conditions I1-I2 hold, and that the parameter space Θ is compact. Then, if $\hat{\theta}_n$ defined in (9) is consistent and \tilde{I}_0 is nonsingular, we have

$$(59) \quad \theta_n^D - \theta_0 = O_P(n^{-\psi}),$$

$$(60) \quad \theta_n^S - \theta_0 = O_P(n^{-\psi}),$$

where $\theta_n^D = \arg \max_{\theta \in \mathcal{D}_n} \hat{S}_n(\theta)$ and $\theta_n^S = \arg \max_{\theta \in \mathcal{S}_n} \hat{S}_n(\theta)$.

Theorems 1-2 together with the above Theorem 5 offer rigorous statistical analysis for the general iterative semiparametric estimation algorithm presented in Introduction section. Those theorems indicate a tradeoff between the computational cost of searching for an initial estimate, i.e. $\text{card}(\mathcal{D}_n)$ or $\text{card}(\mathcal{S}_n)$, and that of generating an efficient estimate, i.e., k^* . Theorem 5 can be applied to all the examples we have considered. Specifically, Condition I1 is verified for Examples 1-2 in [14], and we can easily verify Condition I1 in Example 3 by adapting the consistency proof of $\hat{\theta}_n$ in [36], see its Proposition 1. In fact, the Conditions I1-I2 are very mild and can be satisfied in a wide range of semiparametric models, e.g., proportional odds model and penalized semiparametric logistic regression.

APPENDIX

A.1. *Conditions M1-M4 on the Least Favorable Submodel.* The LFS in Section 3 is constructed in the following manner. We first assume the existence of a smooth map from the neighborhood of θ into \mathcal{H} , of the form

$t \mapsto \eta_t(\theta, \eta)$, such that the map $t \mapsto \ell(t, \theta, \eta)(x)$ can be defined as follows:

$$(A.1) \quad \ell(t, \theta, \eta)(x) = \log \text{lik}(t, \eta_t(\theta, \eta))(x),$$

where we require $\eta_\theta(\theta, \eta) = \eta$ for all $(\theta, \eta) \in \Theta \times \mathcal{H}$. Thus, $\log pl_n(\theta) = \sum_{i=1}^n \ell(X_i; \theta, \theta, \hat{\eta}(\theta))$. See [14] for similar constructions. We define $\dot{\ell}(t, \theta, \eta)$, $\ddot{\ell}(t, \theta, \eta)$ and $\ell^{(3)}(t, \theta, \eta)$ as the first, second and third derivative of $\ell(t, \theta, \eta)$ with respect to t , respectively. Also denote $\ell_{t,\theta}(t, \theta, \eta)$ as $(\partial^2 / \partial t \partial \theta) \ell(t, \theta, \eta)$.

- M1. We assume that the derivatives $(\partial^{l+m} / \partial t^l \partial \theta^m) \ell(t, \theta, \eta)$ have integrable envelop functions in $L_1(P)$ for $(l+m) \leq 3$, and that the Fréchet derivatives of $\eta \mapsto \ddot{\ell}(\theta_0, \theta_0, \eta)$ and $\eta \mapsto \ell_{t,\theta}(\theta_0, \theta_0, \eta)$ are bounded around η_0 ;
- M2. $P \dot{\ell}(\theta_0, \theta_0, \eta) = O(\|\eta - \eta_0\|^2)$ for all η around η_0 ;
- M3. $\sqrt{n}(\mathbb{P}_n - P)(\dot{\ell}(\theta_0, \theta_0, \hat{\eta}(\tilde{\theta}_n)) - \dot{\ell}(\theta_0, \theta_0, \eta_0)) = O_P(n^{-2r+1/2} \vee n^{1/2-r} \|\tilde{\theta}_n - \theta_0\|)$ for any $\tilde{\theta}_n \xrightarrow{P} \theta_0$;
- M4. The classes of functions $\{\ddot{\ell}(t, \theta, \eta)(x) : (t, \theta, \eta) \in V\}$ and $\{\ell_{t,\theta}(t, \theta, \eta)(x) : (t, \theta, \eta) \in V\}$ are P -Donsker, and $\{\ell^{(3)}(t, \theta, \eta)(x) : (t, \theta, \eta) \in V\}$ is P -Glivenko-Cantelli, where V is some neighborhood of $(\theta_0, \theta_0, \eta_0)$.

See Section 2.2 of [14] for the discussions on M1-M4.

A.2. Useful Lemmas. The first two Lemmas are used in the proof of Theorem 1. The Lemmas A.3, A.4, A.5 and A.6 are used in the proofs of Theorem 2, Corollary 1, Theorem 3 and Corollary 2, respectively.

LEMMA A.1. *Suppose that Conditions M1-M4 and (13) hold. If $\tilde{\theta}_n$ is*

n^ψ -consistent, then we have

$$\begin{aligned} (\text{A.2}) \quad \widehat{\mathcal{Y}}_n(\tilde{\theta}_n, s_n) &= \mathbb{P}_n \tilde{\ell}_0 + O_P \left(n^{-\psi} \vee |s_n| \vee \frac{g_r(n^{-\psi} \vee |s_n|)}{n|s_n|} \right), \\ \widehat{\ell}_n(\widehat{\theta}_n + U_n, s_n) &= \widehat{\ell}_n(\widehat{\theta}_n, s_n) - \tilde{I}_0 U_n \\ (\text{A.3}) \quad &+ O_P \left(\frac{g_r(|s_n| \vee \|U_n\|) \vee n^{1/2-2r}}{n|s_n|} \right), \end{aligned}$$

$$\begin{aligned} \widehat{I}_n(\tilde{\theta}_n, t_n) &= \tilde{I}_0 \\ (\text{A.4}) \quad &+ O_P \left(\frac{g_r(\|\tilde{\theta}_n - \widehat{\theta}_n\| \vee |t_n|) \vee nt_n \|\tilde{\theta}_n - \widehat{\theta}_n\| \vee n^{1/2-2r}}{nt_n^2} \right), \end{aligned}$$

where $g_r(t) = nt^3 \vee n^{1-2r}t$ and $U_n = O_P(n^{-s})$ for some $s > 0$.

PROOF: Under the assumptions M1-M4 and (13), [14] proved the following asymptotic expansion of $\log pl_n(\bar{\theta}_n)$, where $\bar{\theta}_n$ is consistent,

$$\begin{aligned} \log pl_n(\bar{\theta}_n) &= \log pl_n(\theta_0) + (\bar{\theta}_n - \theta_0)' \sum_{i=1}^n \tilde{\ell}_0(X_i) - \frac{n}{2} (\bar{\theta}_n - \theta_0)' \tilde{I}_0 (\bar{\theta}_n - \theta_0) \\ (\text{A.5}) \quad &+ O_P(g_r(\|\bar{\theta}_n - \theta_0\|)), \end{aligned}$$

$$\begin{aligned} \log pl_n(\bar{\theta}_n) &= \log pl_n(\widehat{\theta}_n) - \frac{1}{2} n (\bar{\theta}_n - \widehat{\theta}_n)' \tilde{I}_0 (\bar{\theta}_n - \widehat{\theta}_n) \\ (\text{A.6}) \quad &+ O_P(g_r(\|\bar{\theta}_n - \widehat{\theta}_n\|) \vee n^{1/2-2r}). \end{aligned}$$

We first prove (A.3). (A.6) implies that

$$\begin{aligned} \log pl_n(\widehat{\theta}_n + V_n + s_n v_i) &= \log pl_n(\widehat{\theta}_n) - \frac{n}{2} (V_n + s_n v_i)' \tilde{I}_0 (V_n + s_n v_i) \\ &+ O_P(g_r(|s_n| \vee \|V_n\|) \vee n^{1/2-2r}), \\ \log pl_n(\widehat{\theta}_n + V_n) &= \log pl_n(\widehat{\theta}_n) - \frac{n}{2} V_n' \tilde{I}_0 V_n + O_P(g_r(\|V_n\|) \vee n^{1/2-2r}), \end{aligned}$$

for any random vector $V_n = o_P(1)$ and $s_n \xrightarrow{P} 0$. Combining the above two expansions and (11), we have

$$[\widehat{\ell}_n(\widehat{\theta}_n + V_n, s_n)]_i = -\frac{s_n}{2} v_i' \tilde{I}_0 v_i - v_i' \tilde{I}_0 V_n + O_P \left(\frac{g_r(|s_n| \vee \|V_n\|) \vee n^{1/2-2r}}{n|s_n|} \right).$$

By taking $V_n = 0$ and U_n , respectively, in the above equation, we have proved (A.3). Following similar analysis in the above, (11) & (A.5) yield (A.2), and (12) & (A.6) yield (A.4). This completes the whole proof. \square

LEMMA A.2. *Suppose that Conditions M1-M4 and (13) hold. If*

$$(A.7) \quad \widehat{I}_n(\widehat{\theta}_n^{(k-1)}, t_n) - \widetilde{I}_0 = O_P(r_n^{(k-1)}),$$

then we have $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\| =$

$$(A.8) \quad O_P \left(|s_n| \vee \|\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n\| r_n^{(k-1)} \vee \frac{g_r(|s_n| \vee \|\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n\|) \vee n^{1/2-2r}}{n|s_n|} \right)$$

for $k = 1, 2, \dots$

PROOF: Based on (10), we have

$$(A.9) \quad \begin{aligned} \widehat{I}_n(\widehat{\theta}_n^{(k-1)}, t_n) \sqrt{n}(\widehat{\theta}_n^{(k)} - \widehat{\theta}_n) &= \left[\sqrt{n} \widehat{I}_n(\widehat{\theta}_n^{(k-1)}, t_n) (\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n) \right] + \sqrt{n} \widehat{\ell}_n(\widehat{\theta}_n, s_n) \\ &+ \left[\sqrt{n} (\widehat{\ell}_n(\widehat{\theta}_n^{(k-1)}, s_n) - \widehat{\ell}_n(\widehat{\theta}_n, s_n)) \right]. \end{aligned}$$

The second term in (A.9) equals to

$$O_P \left(\sqrt{n} |s_n| \vee \frac{g_r(|s_n|) \vee n^{1/2-2r}}{\sqrt{n} |s_n|} \right)$$

according to (11) and (A.6). The third term in (A.9) can be written as

$$-\sqrt{n} \widetilde{I}_0(\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n) + O_P \left(\frac{g_r(|s_n| \vee \|\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n\|) \vee n^{1/2-2r}}{\sqrt{n} |s_n|} \right).$$

for $k = 1, 2, \dots$ by replacing U_n with $(\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n)$ in (A.3). Combining the above analysis, the assumption (A.7) and nonsingularity of \widetilde{I}_0 , we complete the proof of (A.8). \square

LEMMA A.3. *Suppose that Condition G holds. If $\tilde{\theta}_n$ is a n^ψ -consistent estimator for $0 < \psi \leq 1/2$, then we have*

$$\begin{aligned} & n^{-1}[\hat{S}_n^{(1)}(\tilde{\theta}_n) - \hat{S}_n^{(1)}(\theta_0)] \\ (A.10) \quad &= -\tilde{I}_0(\tilde{\theta}_n - \theta_0) + O_P((n^{-g} \vee \|\tilde{\theta}_n - \theta_0\|)\|\tilde{\theta}_n - \theta_0\|), \end{aligned}$$

$$\begin{aligned} & n^{-1}[\hat{S}_n^{(1)}(\tilde{\theta}_n + U_n) - \hat{S}_n^{(1)}(\tilde{\theta}_n)] \\ (A.11) \quad &= -\tilde{I}_0 U_n + O_P((n^{-g} \vee \|\tilde{\theta}_n - \theta_0\|)\|U_n\|), \end{aligned}$$

where U_n a statistic of the order $O_P(n^{-s})$ for some $s \geq \psi$.

PROOF: We first consider (A.10). Using a Taylor's expansion, we have

$$\begin{aligned} \frac{1}{n}\hat{S}_n^{(1)}(\tilde{\theta}_n) &= \frac{1}{n}\hat{S}_n^{(1)}(\theta_0) + \frac{1}{n}\hat{S}_n^{(2)}(\theta_0)(\tilde{\theta}_n - \theta_0) \\ &\quad + \frac{1}{2}(\tilde{\theta}_n - \theta_0) \otimes \frac{\hat{S}_n^{(3)}(\theta_1^*)}{n} \otimes (\tilde{\theta}_n - \theta_0) \\ &= \frac{1}{n}\hat{S}_n^{(1)}(\theta_0) + A + B, \end{aligned}$$

where θ_1^* lies between $\tilde{\theta}_n$ and θ_0 . In view of (8) and (22), we have $A = -\tilde{I}_0(\tilde{\theta}_n - \theta_0) + O_P(n^{-g}\|\tilde{\theta}_n - \theta_0\|)$. Condition (23) implies that $B = O_P(\|\tilde{\theta}_n - \theta_0\|^2)$. This completes the proof of (A.10). We next consider (A.11). Similarly, we have $[\hat{S}_n^{(1)}(\tilde{\theta}_n + U_n) - \hat{S}_n^{(1)}(\tilde{\theta}_n)]/n$

$$\begin{aligned} &= \frac{1}{n}\hat{S}_n^{(2)}(\tilde{\theta}_n)U_n + O_P(\|U_n\|^2) \\ &= \frac{1}{n}S_n^{(2)}(\tilde{\theta}_n)U_n + O_P(n^{-g}\|U_n\| \vee \|U_n\|^2), \\ &= \frac{1}{n}S_n^{(2)}(\theta_0)U_n + O_P(\|\tilde{\theta}_n - \theta_0\|\|U_n\| \vee n^{-g}\|U_n\| \vee \|U_n\|^2), \\ &= -\tilde{I}_0 U_n + O_P(n^{-1/2}\|U_n\| \vee \|\tilde{\theta}_n - \theta_0\|\|U_n\| \vee n^{-g}\|U_n\| \vee \|U_n\|^2), \end{aligned}$$

where the second equation follows from (22), the third equality follows from (23) and the last equation follows from CLT and (8). Considering that $1/4 < g \leq 1/2$ and $s \geq \psi$, we have proved (A.11). \square

LEMMA A.4. Let $\widehat{S}_n(\theta) = \sum_{i=1}^n \ell_\theta(X_i)$. Suppose that $\widetilde{\theta}_n$ is a n^ψ -consistent estimator for $0 < \psi \leq 1/2$. If $\ell_\theta(\cdot)$ satisfies P1 & P2, we have

$$\begin{aligned} & n^{-1}[\widehat{S}_n^{(1)}(\widetilde{\theta}_n) - \widehat{S}_n^{(1)}(\theta_0)] \\ (A.12) \quad &= -I_0(\widetilde{\theta}_n - \theta_0) + O_P(\|\widetilde{\theta}_n - \theta_0\|^2), \end{aligned}$$

$$\begin{aligned} & n^{-1}[\widehat{S}_n^{(1)}(\widetilde{\theta}_n + U_n) - \widehat{S}_n^{(1)}(\widetilde{\theta}_n)] \\ (A.13) \quad &= -I_0 U_n + O_P(\|\widetilde{\theta}_n - \theta_0\| \|U_n\|), \end{aligned}$$

where U_n a statistic of the order $O_P(n^{-s})$ for any $s \geq \psi$.

PROOF: We only provide the proof of (A.13) since that of (A.12) is completely analogous and simpler. To show (A.13), it suffices to prove that, for every $C_1, C_2 > 0$ and $s \geq \psi$,

$$\begin{aligned} & \sup_{|t| \leq C_1, |u| \leq C_2} \left| n^{-1} \left[\widehat{S}_n^{(1)}(\theta_0 + n^{-\psi}t + n^{-s}u) - \widehat{S}_n^{(1)}(\theta_0 + n^{-\psi}t) \right] + n^{-s}I_0 u \right| \\ &= O_P(n^{-s-\psi}). \end{aligned}$$

Denote $Z_n(t, u) = n^{-1/2}[\widehat{S}_n^{(1)}(\theta_0 + n^{-\psi}t + n^{-s}u) - \widehat{S}_n^{(1)}(\theta_0 + n^{-\psi}t)]$ and $Z_n^0(t, u) = Z_n(t, u) - EZ_n(t, u)$. Then, it suffices to show that

$$(A.14) \quad \sup_{|t| \leq C_1, |u| \leq C_2} |Z_n^0(t, u)| = O_P(n^{1/2-\psi-s}),$$

$$(A.15) \quad \sup_{|t| \leq C_1, |u| \leq C_2} |EZ_n(t, u) + n^{1/2-s}I_0 u| = O_P(n^{1/2-\psi-s}).$$

The proofs of (A.14) and (A.15) are similar as those of (2.3) and (2.4) in Page 1224 of [25], and are thus skipped. \square

LEMMA A.5. *Suppose Conditions K1-K2 & C1-C2 hold. Then we have*

$$(A.16) \quad \frac{1}{\sqrt{n}} \sum_{i=1}^n \left(\frac{\partial}{\partial \theta} \Big|_{\theta=\theta_0} A_{\theta, \eta(\theta)} \right) [\hat{\eta}_0 - \eta_0](X_i) = O_P(n^{-\delta}),$$

$$(A.17) \quad \frac{1}{\sqrt{n}} \sum_{i=1}^n A_{\theta_0, \eta_0} [\hat{\eta}_0^{(1)} - \eta_0^{(1)}](X_i) = O_P(n^{-\delta}),$$

$$(A.18) \quad \frac{1}{\sqrt{n}} \dot{r}_n(\theta_0) = O_P(n^{1/2-2g}),$$

where $r_n(\theta) \equiv \hat{S}_n(\theta) - S_n(\theta) - \sum_{i=1}^n A_{\theta, \eta(\theta)} [\hat{\eta}(\theta) - \eta(\theta)]$.

PROOF: The proof of Lemma 2 in [36] directly implies (A.16) and (A.17).

As for (A.18), by Taylor expansion, we first rewrite

$$\begin{aligned} r_n(\theta) &= \frac{1}{2} \sum_{i=1}^n \int_0^1 \frac{\partial^2 \log \text{lik}}{\partial \lambda^2}(X_i; \theta, \eta_t(\theta)(Z_i)) dt \{ \hat{\eta}(\theta)(Z_i) - \eta(\theta)(Z_i) \}^2 \\ &\equiv \frac{1}{2} \sum_{i=1}^n Q_\theta(X_i) \{ \hat{\eta}(\theta)(Z_i) - \eta(\theta)(Z_i) \}^2, \end{aligned}$$

where $\eta_t(\theta)(Z_i) = \eta(\theta)(Z_i) + t(\hat{\eta}(\theta) - \eta(\theta))(Z_i)$. To prove (A.18), it suffices to show that

$$(A.19) \quad \sup_{z \in \mathcal{Z}} \left| \frac{1}{n} \sum_{i=1}^n \frac{\partial^j}{\partial \theta^j} \Big|_{\theta=\theta_0} Q_\theta(X_i) \right| = O_P(1) \quad \text{for } j = 0, 1$$

in view of (37). For $j = 0$, we have

$$|Q_{\theta_0}(x)| \leq \sup_{\lambda \in H} \left| \frac{\partial^2 \log \text{lik}}{\partial \lambda^2}(x; \theta_0, \lambda) \right| = O_P(1) \quad \text{for all } z \in \mathcal{Z}$$

based on the smoothness Condition K2. The case $j = 1$ can be established similarly. \square

LEMMA A.6. *Let $\eta_0(\mathbf{z}) = (\eta_0(z_1), \dots, \eta_0(z_n))'$ and $\epsilon = (\epsilon_1, \dots, \epsilon_n)'$. If*

$\lambda_n \rightarrow 0$, then we have

$$(A.20) \quad \mathbf{w}'A(\lambda_n)\epsilon = O_P(\lambda_n^{-1/(2k)}),$$

$$(A.21) \quad \mathbf{w}'[I - A(\lambda_n)]\eta_0(\mathbf{z}) = O_P(n^{1/2}\lambda_n),$$

$$(A.22) \quad \mathbf{w}'(I - A(\lambda_n))\mathbf{w}/n = \Sigma + O_P(n^{-1/2} \vee n^{-1}\lambda_n^{-1/k}).$$

PROF: We first state the Lemmas 4.1 and 4.3 in [17]:

$$(A.23) \quad n^{-1} \sum_{l=1}^n [(I - A(\lambda_n))\eta_0(\mathbf{z})]_l^2 \leq \lambda_n^2 J^2(\eta_0),$$

$$(A.24) \quad tr(A(\lambda_n)) = O(\lambda_n^{-1/k}),$$

$$(A.25) \quad tr(A^2(\lambda_n)) = O(\lambda_n^{-1/k}).$$

Since $Var[(\mathbf{w}'A(\lambda_n)\epsilon)_i] = \sigma^2 \Sigma_{ii} tr(A^2(\lambda_n))$, we can show that $[\mathbf{w}'A(\lambda_n)\epsilon]_i = O_P(\lambda_n^{-1/2k})$ based on (A.25), thus proved (A.20). We next consider (A.21) by establishing that $Var[\mathbf{w}'\{I - A(\lambda_n)\}\eta_0(\mathbf{z})]_i = \Sigma_{ii}\eta_0'(\mathbf{z})[I - A(\lambda_n)]^2\eta_0(\mathbf{z})$. Then, we can prove (A.21) by (A.23). As for (A.22), we first write (A.22) as the sum of

$$\Sigma + (\mathbf{w}'\mathbf{w}/n - \Sigma) - \mathbf{w}'A(\lambda_n)\mathbf{w}/n,$$

where the second term is $O_P(n^{-1/2})$ based on the central limit theorem. For the last term, we have $E\{[\mathbf{w}'A(\lambda_n)\mathbf{w}]_{ij}\}^2 =$

$$\begin{aligned} & (\Sigma_{ij})^2 (tr(A(\lambda_n)))^2 + (\Sigma_{ii}\Sigma_{jj} + (\Sigma_{ij})^2) tr(A^2(\lambda_n)) \\ & + (E(X_{1i}X_{1j})^2 - 2(\Sigma_{ij})^2 - \Sigma_{ii}\Sigma_{jj}) \sum_r A_{rr}^2(\lambda_n) \end{aligned}$$

for $i \neq j$. When $i = j$, we have $E|(\mathbf{w}'A(\lambda_n)\mathbf{w})_{ii}| = \Sigma_{ii} tr(A(\lambda_n))$. By considering (A.24)-(A.25), we have proved (A.22). \square

A.3. *Proof of Theorem 1.* (14) follows from Theorem 2 in [14]. We next prove (15). By (A.4) in Lemma A.1 and (A.8) in Lemma A.2, we obtain that

$$\begin{aligned}
\widehat{\theta}_n^{(k)} - \widehat{\theta}_n &= O_P \left(\frac{g_r \left(|t_n| \vee \|\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n\| \right) \vee nt_n \|\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n\| \vee n^{1/2-2r}}{nt_n^2} \times \right. \\
&\quad \left. \|\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n\| \vee |s_n| \vee \frac{g_r \left(|s_n| \vee \|\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n\| \right) \vee n^{1/2-2r}}{n|s_n|} \right) \\
&= O_P \left(\left(|t_n| \vee \frac{n^{-2r} \vee n^{-r_{k-1}}}{|t_n|} \vee \frac{n^{-3r_{k-1}} \vee n^{-2r-r_{k-1}} \vee n^{-1/2-2r}}{|t_n|^2} \right) \right. \\
&\quad \left. \times n^{-r_{k-1}} \vee \frac{n^{-3r_{k-1}} \vee n^{-2r-r_{k-1}} \vee n^{-1/2-2r}}{|s_n|} \vee |s_n| \vee n^{-2r} \right) \\
\text{(A.26)} &= O_P \left(f_{k-1}(|t_n|) \vee h_{k-1}(|s_n|) \vee n^{-2r} \right),
\end{aligned}$$

where $\|\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n\|$ is defined as $O_P(n^{-r_{k-1}})$. To analyze the order of (A.26), we have to consider three different cases: (i) $r_{k-1} < r$; (ii) $r \leq r_{k-1} < 1/2$; (iii) $r_{k-1} \geq 1/2$. For the case (i), the smallest order of f_{k-1} , i.e., $n^{-3r_{k-1}/2}$, is achieved by taking $|t_n| \asymp n^{-r_{k-1}/2}$, and the smallest order of h_{k-1} , i.e., $n^{-3r_{k-1}/2}$, is achieved by taking $|s_n| \asymp n^{-3r_{k-1}/2}$. Therefore, $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\| = O_P(\|\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n\|^{3/2}) = O_P(n^{-S_1(\psi, k)})$ if $k \leq K_1(\psi, r)$. For the case (ii), the smallest order of f_{k-1} , i.e., $n^{-3r_{k-1}/2}$, is achieved by taking $|t_n| \asymp n^{-r_{k-1}/2}$, and the smallest order of h_{k-1} , i.e., $n^{-(2r+r_{k-1})/2}$, is achieved by taking $|s_n| \asymp n^{-(2r+r_{k-1})/2}$. Therefore, $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\| = O_P(\|\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n\|^{1/2} n^{-r})$ if $r \leq r_{k-1} < 1/2$. This implies that $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\| = O_P(n^{-S_2(\psi, r, k)})$ if $r \leq \psi < 1/2$. It is easy to show that $S_2(\psi, r, k) \geq 1/2$ if $k \geq K_2(\psi, r, 1/2)$. Now we consider the case (iii). In this case, the smallest order of f_{k-1} , i.e., $n^{-3r_{k-1}/2}$, is achieved by taking $|t_n| \asymp n^{-r_{k-1}/2}$, and the smallest order of h_{k-1} , i.e., $n^{-r-1/4}$, is achieved by taking $|s_n| \asymp n^{-r-1/4}$. Therefore, we know that the smallest order of $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\|$ is $O_P(n^{-r-1/4})$ in this case. Combining the

analysis of (i)-(iii), we can conclude that the convergence rate of $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\|$ is continuously improving till the optimal bound $O_P(n^{-r-1/4})$ and can be expressed as $O_P(n^{-S(\psi, r, k)})$. (16) also follows from the above analysis. \square

A.4. Proof of Theorem 2. We first show (26) by applying Lemma A.3. In (A.10), we replace $\widetilde{\theta}_n$ by $\widehat{\theta}_n$. Since $\widehat{\theta}_n$ is assumed to be consistent and θ_0 is an interior point of Θ , we have $\widehat{S}_n^{(1)}(\widehat{\theta}_n) = 0$. By (5) and (21), we have

$$(A.27) \quad \sqrt{n}(\widehat{\theta}_n - \theta_0) = \sqrt{n}\widetilde{I}_0^{-1}\mathbb{P}_n\widetilde{\ell}_0 + O_P(n^{1/2-2g} \vee n^{1/2}\|\widehat{\theta}_n - \theta_0\|^2)$$

given that $\widehat{\theta}_n$ is consistent and \widetilde{I}_0 is nonsingular. Considering the range of g , we can show $\widehat{\theta}_n$ is actually \sqrt{n} -consistent, and thus simplify (A.27) to (26).

We next show (27). By (18), we can write $\sqrt{n}\widehat{I}_n(\widehat{\theta}_n^{(0)})(\widehat{\theta}_n^{(1)} - \widehat{\theta}_n)$ as

$$\begin{aligned} & \sqrt{n}\widehat{I}_n(\widehat{\theta}_n^{(0)})(\widehat{\theta}_n^{(0)} - \widehat{\theta}_n) + n^{1/2}(\widehat{\ell}_n(\widehat{\theta}_n^{(0)}) - \widehat{\ell}_n(\widehat{\theta}_n)) \\ &= \sqrt{n}\widehat{I}_n(\widehat{\theta}_n^{(0)})(\widehat{\theta}_n^{(0)} - \widehat{\theta}_n) + n^{-1/2}\widehat{S}_n^{(2)}(\widehat{\theta}_n^{(0)})(\widehat{\theta}_n^{(0)} - \widehat{\theta}_n) + O_P(\sqrt{n}\|\widehat{\theta}_n - \widehat{\theta}_n^{(0)}\|^2) \\ &= O_P(\sqrt{n}\|\widehat{\theta}_n - \widehat{\theta}_n^{(0)}\|^2) \end{aligned}$$

under Condition G. Further, by (22) and (23), we have the invertibility of $\widehat{I}_n(\widehat{\theta}_n^{(0)})$ based on that of \widetilde{I}_0 . This implies $\widehat{\theta}_n^{(1)} - \widehat{\theta}_n = O_P(\|\widehat{\theta}_n^{(0)} - \widehat{\theta}_n\|^2)$. By the induction principal, we can thus show

$$(A.28) \quad \widehat{\theta}_n^{(k)} - \widehat{\theta}_n = O_P(\|\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n\|^2) \text{ for any } k \geq 1.$$

(27) follows from (A.28) trivially.

To show (28), we first prove $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\| =$

$$(A.29) \quad O_P\left(n^{1/2-g}\|\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n\|^2 \vee n^{-g}\|\widehat{\theta}_n^{(k-1)} - \widehat{\theta}_n\|\right).$$

By replacing $\tilde{\theta}_n$ and U_n with $\hat{\theta}_n$ and $(\hat{\theta}_n^{(k-1)} - \hat{\theta}_n)$ in (A.11), respectively, we establish that $n^{-1/2}[\hat{S}_n^{(1)}(\hat{\theta}_n^{(k-1)}) - \hat{S}_n^{(1)}(\hat{\theta}_n)] =$

$$(A.30) \quad -\sqrt{n}\tilde{I}_0(\hat{\theta}_n^{(k-1)} - \hat{\theta}_n) + O_P(n^{1/2-g}\|\hat{\theta}_n^{(k-1)} - \hat{\theta}_n\|).$$

Similarly, by setting $\tilde{\theta}_n$ as $\hat{\theta}_n$, and then setting U_n as $(\hat{\theta}_n^{(k-1)} - \hat{\theta}_n + n^{-1/2}t_1v_j)$ and $(\hat{\theta}_n^{(k-1)} - \hat{\theta}_n + n^{-1/2}t_2v_j)$ in (A.11), respectively, we have that

$$(A.31) \quad [\hat{I}_n(\hat{\theta}_n^{(k-1)})]_{ij} = [\tilde{I}_0]_{ij} + O_P(n^{1/2-g}\|\hat{\theta}_n^{(k-1)} - \hat{\theta}_n\| \vee n^{-g})$$

when $\tilde{I}_0^{(k-1)}$ is defined in (20). Following similar logic in analyzing (A.28), we can obtain (A.29) by considering (A.30)-(A.31). Next we will show that (A.29) implies (28) by the following analysis. Based on (A.29) we have

$$(A.32) \quad \|\hat{\theta}_n^{(k)} - \hat{\theta}_n\| = \begin{cases} O_P(n^{-g}\|\hat{\theta}_n^{(k-1)} - \hat{\theta}_n\|) & \text{if } \|\hat{\theta}_n^{(k-1)} - \hat{\theta}_n\| = O_P(n^{-1/2}), \\ O_P(n^{1/2-g}\|\hat{\theta}_n^{(k-1)} - \hat{\theta}_n\|^2) & \text{if } \|\hat{\theta}_n^{(k-1)} - \hat{\theta}_n\|^{-1} = O_P(n^{1/2}). \end{cases}$$

It is easy to show that $\|\hat{\theta}_n^{(L_1(\psi,g))} - \hat{\theta}_n\| = O_P(n^{-1/2})$ and $\|\hat{\theta}_n^{(L_1(\psi,g)-1)} - \hat{\theta}_n\|^{-1} = O_P(n^{1/2})$. In other words, if $k \leq L_1(\psi, g)$, then we have the relation that $\|\hat{\theta}_n^{(k)} - \hat{\theta}_n\| = O_P(n^{1/2-g}\|\hat{\theta}_n^{(k-1)} - \hat{\theta}_n\|^2)$ based on (A.32). This implies the form of $R_1(\psi, g, k)$ in (25). Note that $R_1(\psi, g, k)$ is an increasing function of k under the condition that $\psi + g > 1/2$. After $L_1(\psi, g)$ iterations, we have

$$(A.33) \quad \|\hat{\theta}_n^{(L_1(\psi,g))} - \hat{\theta}_n\| = O_P(n^{-R_1(\psi,g,L_1(\psi,g))}) = O_P(n^{-1/2}).$$

Thus, we have the relation that $\|\hat{\theta}_n^{(k)} - \hat{\theta}_n\| = O_P(n^{-g}\|\hat{\theta}_n^{(k-1)} - \hat{\theta}_n\|)$ for $k \geq (L_1(\psi, g) + 1)$ based on (A.32). Combining this relation with (A.33), we can show the form of $R_2(\psi, g, k)$ when $k > L_1(\psi, g)$. Since $R(\psi, g, k)$ is an increasing function of k given that $1/2 - g < \psi \leq 1/2$, the stochastic order

of $\|\widehat{\theta}_n^{(k)} - \widehat{\theta}_n\|$ is continuously decreasing as $k \rightarrow \infty$. The calculation of k^* also follows from the above analysis. \square

A.5. *Proof of Theorem 3.* We first consider (21) by rewriting its LHS as

$$\frac{1}{n} \frac{\partial}{\partial \theta} \Big|_{\theta=\theta_0} \left[\sum_{i=1}^n A_{\theta, \eta(\theta)} [\widehat{\eta}(\theta) - \eta(\theta)](X_i) + r_n(\theta) \right],$$

where $r_n(\theta)$ is defined in Lemma A.5. Therefore, we have

$$\begin{aligned} & n^{-1} [\widehat{S}_n^{(1)}(\theta_0) - S_n^{(1)}(\theta_0)] \\ &= \frac{1}{n} \sum_{i=1}^n \left(\frac{\partial}{\partial \theta} \Big|_{\theta=\theta_0} A_{\theta, \eta(\theta)} \right) (\widehat{\eta}_0 - \eta_0) + \frac{1}{n} \sum_{i=1}^n A_{\theta_0, \eta_0} (\widehat{\eta}_0^{(1)} - \eta_0^{(1)}) + \frac{1}{n} \dot{r}_n(\theta_0) \\ &= O_P(n^{-2g}) \end{aligned}$$

by Lemma A.5 and the condition that $\delta \geq (2g - 1/2)$. As discussed previously, we will show (22) together with (24). By Taylor expansion, we have

$$\begin{aligned} \widehat{S}_n(\theta) - S_n(\theta) &= \sum_{i=1}^n \int_0^1 \frac{\partial \log \text{lik}}{\partial \lambda} (X_i; \theta, \eta_t(\theta)(Z_i)) dt [\widehat{\eta}(\theta)(Z_i) - \eta(\theta)(Z_i)] \\ &\equiv \sum_{i=1}^n R_\theta(X_i) [\widehat{\eta}(\theta)(Z_i) - \eta(\theta)(Z_i)]. \end{aligned}$$

Hence, to prove (22) and (24), it suffices to show that

$$(A.34) \quad \sup_{\theta \in \mathcal{N}(\theta_0)} \sup_{z \in \mathcal{Z}} \left| n^{-1} \sum_{i=1}^n \frac{\partial^j}{\partial \theta^j} R_\theta(X_i) \right| = O_P(1) \quad \text{for } j = 0, 1, 2, 3$$

in view of (37) and (38). Considering the smoothness Condition K2, we can prove (A.34) using the same approach as in the proof of (A.19).

In the end, it remains to show that the class of functions

$$\{(\partial^3 / \partial \theta^3) \log \text{lik}(x; \theta, \eta(\theta)) : \theta \in \mathcal{N}(\theta_0)\}$$

is P-Glivenko-Cantelli and that

$$(A.35) \quad \sup_{\theta \in \mathcal{N}(\theta_0)} E \left| (\partial^3 / \partial \theta^3) \log \text{lik}(X; \theta, \eta(\theta)) \right| < \infty.$$

Let $\ell^{(3)}(\theta, \eta(\theta)) = (\partial^3/\partial\theta^3) \log \text{lik}(x; \theta, \eta(\theta))$. For any $\theta_1, \theta_2 \in \mathcal{N}(\theta_0)$, we have $|\ell^{(3)}(\theta_1, \eta(\theta_1)) - \ell^{(3)}(\theta_2, \eta(\theta_2))|$

$$\begin{aligned} &\leq \sup_{\theta, \lambda} \left| \frac{\partial \ell^{(3)}}{\partial \theta}(\theta, \lambda) \right| \|\theta_1 - \theta_2\| + \sup_{\theta, \lambda} \left| \frac{\partial \ell^{(3)}}{\partial \lambda}(\theta, \lambda) \right| \|\eta(\theta_1) - \eta(\theta_2)\|_\infty \\ &\leq \sup_{\theta, \lambda} \left| \frac{\partial \ell^{(3)}}{\partial \theta}(\theta, \lambda) \right| \|\theta_1 - \theta_2\| + \sup_{\theta, \lambda} \left| \frac{\partial \ell^{(3)}}{\partial \lambda}(\theta, \lambda) \right| \sup_{\theta \in \mathcal{N}(\theta_0)} \|\eta^{(1)}(\theta)\|_\infty \\ &\quad \times \|\theta_1 - \theta_2\| \\ &\leq A \|\theta_1 - \theta_2\|. \end{aligned}$$

By Condition K2 and $\sup_{\theta \in \mathcal{N}(\theta_0)} \|\eta^{(1)}(\theta)\|_\infty < \infty$ in Condition C1, we know that $EA^2 < \infty$. Thus, by the P-G-C preservation Theorem 9.23 of [26] and compactness of $\mathcal{N}(\theta_0)$, we know that

$$\{(\partial^3/\partial\theta^3) \log \text{lik}(x; \theta, \eta(\theta)) : \theta \in \mathcal{N}(\theta_0)\}$$

is P-Glivenko-Cantelli. The last condition (A.35) follows from the Conditions K2 and C1 by some algebra. \square

A.6. *Proof of Lemma 1.* Let

$$\widehat{m}_\theta(z) = \frac{\sum_{i=1}^n \psi_\theta(Y_i, W_i) K((z - Z_i)/b_n)}{\sum_{i=1}^n K((z - Z_i)/b_n)}.$$

Note that $\widehat{\eta}(\theta)(z) = \rho(\widehat{m}_\theta(z))$ by (41). Correspondingly, we have $\eta(\theta)(z) = \rho(m_\theta(z))$ based on Lemma 7 of [36]. Following the proof of Lemma 8 in [36], we can derive that

$$\begin{aligned} &\sup_{\theta \in \Theta} \left\| \frac{\partial^{k+j}}{\partial z^k \partial \theta^j} \widehat{m}_\theta(z) - \frac{\partial^{k+j}}{\partial z^k \partial \theta^j} m_\theta(z) \right\|_\infty \\ (A.36) \quad &= O_P \left(n^{-\frac{q}{2q+4}} b_n^{-k-\frac{q+4}{q+2}} n^\epsilon \vee b_n^2 \right) \end{aligned}$$

for any $\epsilon > 0$, $k = 0, 1$ and $j = 0, 1, 2, 3$. Considering (41), (A.36) and Condition (f), we can show that

$$(A.37) \quad \sup_{\theta \in \mathcal{N}(\theta_0)} \|\hat{\eta}^{(s)}(\theta) - \eta^{(s)}(\theta)\|_\infty = O_P \left(n^{-\frac{q}{2q+4}} b_n^{-\frac{q+4}{q+2}} n^\epsilon \vee b_n^2 \right)$$

for $s = 0, 1, 2, 3$ after some algebra. Following similarly logic, we show that

$$(A.38) \quad \left\| \frac{\partial}{\partial z} \hat{\eta}_0(z) - \frac{\partial}{\partial z} \eta_0(z) \right\|_\infty = O_P \left(n^{-\frac{q}{2q+4}} b_n^{-\frac{2q+6}{q+2}} n^\epsilon \vee b_n^2 \right)$$

$$(A.39) \quad \left\| \frac{\partial}{\partial z} \hat{\eta}_0^{(1)}(z) - \frac{\partial}{\partial z} \eta_0^{(1)}(z) \right\|_\infty = O_P \left(n^{-\frac{q}{2q+4}} b_n^{-\frac{2q+6}{q+2}} n^\epsilon \vee b_n^2 \right)$$

Considering (A.37)-(A.39), we complete the whole proof. \square

A.7. Proof of Corollary 2. For the \sqrt{n} consistency of $\hat{\theta}_{\lambda_n}$, it suffices to show that, for any given $\epsilon > 0$, there exists a large constant M such that

$$(A.40) \quad P \left\{ \inf_{\|s\|=M} \Delta_n(s) > 0 \right\} \geq 1 - \epsilon,$$

where $\Delta_n(s) \equiv [\hat{S}_{\lambda_n}(\theta_0 + n^{-1/2}s) - \hat{S}_{\lambda_n}(\theta_0)]$. According to (54), we have

$$\Delta_n(s) \geq \tilde{S}_{\lambda_n}(\theta_0 + n^{-1/2}s) - \tilde{S}_{\lambda_n}(\theta_0) + n\tau_n^2 \sum_{j=1}^q \frac{|\theta_{0j} + n^{-1/2}s_j| - |\theta_{0j}|}{|\tilde{\theta}_j|},$$

where s_j is the j -th element of s . The Taylor expansion further gives

$$(A.41) \quad \begin{aligned} \Delta_n(s) &\geq n^{-1/2} s' \tilde{S}_{\lambda_n}^{(1)}(\theta_0) + \frac{1}{2} s' [\tilde{S}_{\lambda_n}^{(2)}(\theta_0)/n] s \\ &\quad + n\tau_n^2 \sum_{j=1}^q \frac{|\theta_{0j} + n^{-1/2}s_j| - |\theta_{0j}|}{|\tilde{\theta}_j|}, \end{aligned}$$

where $\tilde{S}_{\lambda_n}^{(j)}(\theta_0)$ represents the j -th derivative of $\tilde{S}_{\lambda_n}(\theta)$ at θ_0 . Based on (55), we have

$$(A.42) \quad \tilde{S}_{\lambda_n}^{(1)}(\theta_0) = -2\mathbf{w}'[I - A(\lambda_n)](\mathbf{y} - \mathbf{w}\theta_0),$$

$$(A.43) \quad \tilde{S}_{\lambda_n}^{(2)}(\theta_0) = 2\mathbf{w}'[I - A(\lambda_n)]\mathbf{w}.$$

Lemma A.6 implies that

$$(A.44) \quad \tilde{S}_{\lambda_n}^{(1)}(\theta_0) = O_P(n^{1/2}),$$

$$(A.45) \quad \tilde{S}_{\lambda_n}^{(2)}(\theta_0) = O_P(n)$$

since λ_n is required to converge to zero. Hence, we know the first two terms in the right hand side of (A.41) have the same order, i.e. $O_P(1)$. And the second term, which converges to some positive constant, dominates the first one by choosing sufficiently large M . The third term is bounded by $n^{1/2}\tau_n^2 M_0$ for some positive constant M_0 since $\tilde{\beta}_j$ is the consistent estimate for the nonzero coefficient. Considering that $\sqrt{n}\tau_n^2 \rightarrow 0$, we have shown the \sqrt{n} -consistency of $\hat{\theta}_{\lambda_n}$.

To complete the proof of other parts, we first need to show

$$(A.46) \quad \|\hat{\theta}_{\lambda_n}^{(1)} - \hat{\theta}_{\lambda_n}\| = O_P(n^{-1})$$

based on Theorem 4. And then we will verify Condition G' for the case $c = -2$. It is easy to show that $\mathbb{P}_n \tilde{\ell}_0 = \mathbf{w}'\epsilon/n$ and $\tilde{I}_0 = \Sigma$ in this example.

To verify (47), we have

$$\begin{aligned} & \frac{1}{n} \hat{S}_{\lambda_n}^{(1)}(\theta_0) + 2\mathbb{P}_n \tilde{\ell}_0 \\ &= -\frac{2}{n} \mathbf{w}'(I - A(\lambda_n))\eta_0(\mathbf{z}) + \frac{2}{n} \mathbf{w}' A(\lambda_n)\epsilon + \tau_n^2 \delta_n(\theta_0) \\ &= O_P(n^{-1/2}\lambda_n \vee n^{-1}\lambda_n^{-1/(2k)} \vee \tau_n^2), \end{aligned}$$

where the second equality follows from Lemma A.6 and the fact that $\delta_n(\theta_0) = O_P(1)$. Considering the conditions on τ_n and λ_n , we have proved (47). (48) follows from (A.43) and (A.22), and (49) trivially holds. Having shown the consistency of $\hat{\theta}_{\lambda_n}$ and verified G', we are able to show (A.46).

For any sequence of estimate θ_n , the below arguments show that $\theta_n = 0$ with probability tending to one if it is \sqrt{n} -consistent. For any \sqrt{n} -consistent estimator, it suffices to show that

$$(A.47) \quad \widehat{S}_{\lambda_n}\{(\bar{\theta}_1, 0)\} = \min_{\|\bar{\theta}_2\| \leq Cn^{-1/2}} \widehat{S}_{\lambda_n}\{(\bar{\theta}_1, \bar{\theta}_2)\}$$

for any $\bar{\theta}_1$ satisfying $\|\bar{\theta}_1 - \theta_1\| = O_P(n^{-1/2})$ with probability approaching to 1. In order to show (A.47), we need to show that $\partial \widehat{S}_{\lambda_n}(\theta)/\partial \theta_j < 0$ for $\theta_j \in (-Cn^{-1/2}, 0)$ and $\partial \widehat{S}_{\lambda_n}(\theta)/\partial \theta_j > 0$ for $\theta_j \in (0, Cn^{-1/2})$ holds when $j = q+1, \dots, d$ with probability tending to 1. By two term Taylor expansion of $\widehat{S}_{\lambda_n}(\theta)$ at θ_0 , $\partial \widehat{S}_{\lambda_n}(\theta)/\partial \theta_j$ can be expressed in the following form:

$$\frac{\partial \widehat{S}_{\lambda_n}(\theta)}{\partial \theta_j} = \frac{\partial \widetilde{S}_{\lambda_n}(\theta_0)}{\partial \theta_j} + \sum_{k=1}^d \frac{\partial^2 \widetilde{S}_{\lambda_n}(\theta_0)}{\partial \theta_j \partial \theta_k} (\theta_k - \theta_{0k}) + n\tau_n^2 \frac{1 \times \text{sign}(\theta_j)}{|\widetilde{\theta}_j|},$$

for $j = q+1, \dots, d$. Note that $\|\bar{\theta} - \theta_0\| = O_P(n^{-1/2})$ by the above construction. Hence, we have

$$\frac{\partial \widehat{S}_{\lambda_n}(\theta)}{\partial \theta_j} = O_P(n^{1/2}) + \text{sign}(\theta_j) \frac{n\tau_n^2}{|\widetilde{\theta}_j|}$$

by (A.44) and (A.45). We assume that $n^{k/(2k+1)}\tau_n \rightarrow \tau_0 > 0$ which implies that $\sqrt{n}\tau_n^2/|\widetilde{\theta}_j| \rightarrow \infty$ for \sqrt{n} consistent $\widetilde{\theta}_j$ and $j = q+1, \dots, d$. Thus, we show that the sign of θ_j determines that of $\partial \widehat{S}_{\lambda_n}(\theta)/\partial \theta_j$. The above arguments apply to $\widehat{\theta}_{\lambda_n,2}$ and $\widehat{\theta}_{\lambda_n,2}^{(1)}$ since both of them are proven to be \sqrt{n} consistent in view of the previous discussions, i.e., (A.46).

Now it remains to show the semiparametric efficiency of $\widehat{\theta}_{\lambda_n,1}$, which immediately implies that of $\widehat{\theta}_{\lambda_n,1}^{(1)}$ based on (A.46). Since we have shown $\widehat{\theta}_{\lambda_n,2} = 0$, we can establish that

$$(A.48) \quad \left. \frac{\partial \widehat{S}_{\lambda_n}(\theta)}{\partial \theta_j} \right|_{\theta=(\widehat{\theta}_{\lambda_n,1}, 0)} = 0 \quad \text{for any } j = 1, \dots, q$$

with probability tending to one. Let \mathbf{w}_1 denote the first q columns of \mathbf{w} .

Applying Taylor expansion to (A.48) around θ_0 , we obtain

$$\begin{aligned}
\sqrt{n}(\hat{\theta}_{\lambda_n,1} - \theta_1) &= \sqrt{n} \left\{ \frac{1}{n} \mathbf{w}_1' [I - A(\lambda_n)] \mathbf{w}_1 \right\}^{-1} \frac{1}{n} \mathbf{w}_1' [I - A(\lambda_n)] (\eta_0(\mathbf{z}) + \epsilon) \\
&\quad + O_P(\sqrt{n}\tau_n^2) \\
&= \left\{ \Sigma_{11} + O_P(n^{-1/2} \vee n^{-1}\lambda_n^{-1/k}) \right\}^{-1} \frac{1}{\sqrt{n}} \mathbf{w}_1' \epsilon \\
&\quad + O_P(\sqrt{n}\tau_n^2 \vee n^{-1/2}\lambda_n^{-1/(2k)} \vee \lambda_n) \\
&= \frac{1}{\sqrt{n}} \Sigma_{11}^{-1} \sum_{i=1}^n W_{1i} \epsilon_i + O_P(\sqrt{n}\lambda_n^2 \vee \sqrt{n}\tau_n^2) \\
&\xrightarrow{d} N(0, \sigma^2 \Sigma_{11}^{-1})
\end{aligned}$$

based on (A.42) & (A.43). This completes the whole proof. \square

A.8. *Proof of Theorem 5.* Define $\mathcal{N}_n = \{\theta : \|\theta - \theta_0\| \leq Mn^{-\psi}\}$ and \mathcal{N}_n^c as its complement for any $0 < M < \infty$. Note that $\mathcal{D}_n \cap \mathcal{N}_n \neq \emptyset$ for large enough M and $\mathcal{D}_n \cap \mathcal{N}_n^c \neq \emptyset$ for large enough n . We first consider (59). For

sufficiently large M and any $C_1 > 0$, we have

$$\begin{aligned}
P(\theta_n^D \in \mathcal{N}_n^c) &= P(\theta_n^D \in \mathcal{N}_n^c \text{ and } \theta_{iD} \in \mathcal{N}_n \text{ for some } i) \\
&\leq P\left(\max_{\mathcal{D}_n \cap \mathcal{W}_n} \hat{S}_n(\theta) \leq \max_{\mathcal{D}_n \cap \mathcal{W}_n^c} \hat{S}_n(\theta)\right) \\
&\leq P\left(\max_{\mathcal{D}_n \cap \mathcal{W}_n} \hat{S}_n(\theta) < \hat{S}_n(\theta_0) - C_1 n^{1-2\psi}\right) \\
&\quad + P\left(\left\{\max_{\mathcal{D}_n \cap \mathcal{W}_n} \hat{S}_n(\theta) \leq \max_{\mathcal{D}_n \cap \mathcal{W}_n^c} \hat{S}_n(\theta)\right\} \right. \\
&\quad \left. \cap \left\{\max_{\mathcal{D}_n \cap \mathcal{W}_n} \hat{S}_n(\theta) \geq \hat{S}_n(\theta_0) - C_1 n^{1-2\psi}\right\}\right) \\
&\leq P\left(\max_{\mathcal{D}_n \cap \mathcal{W}_n} n^{-1/2}(\hat{S}_n(\theta) - \hat{S}_n(\theta_0)) < -C_1 n^{1/2-2\psi}\right. \\
&\quad \left. \cap \{\theta_n^o \text{ is consistent}\}\right) \\
&\quad + P\left(\max_{\mathcal{N}_n^c} n^{-1/2}(\hat{S}_n(\theta) - \hat{S}_n(\theta_0)) \geq -C_1 n^{1/2-2\psi}\right) \\
&\quad + P(\theta_n^o \text{ is inconsistent}) \\
&\leq I + II + III,
\end{aligned}$$

where $\theta_n^o = \arg \max_{\mathcal{D}_n \cap \mathcal{W}_n} \hat{S}_n(\theta)$.

The definition of \mathcal{N}_n implies $III \rightarrow 0$ for any M as $n \rightarrow \infty$. We next analyze the term I as follows. In view of (58) and the definition of \mathcal{N}_n , we have that

$$\begin{aligned}
I &= P\left(\sqrt{n}(\theta_n^o - \theta_0)' \mathbb{P}_n \tilde{\ell}_0 - \frac{\sqrt{n}}{2}(\theta_n^o - \theta_0)' \tilde{I}_0(\theta_n^o - \theta_0) + n^{-1/2} \Delta_n(\theta_n^o) \right. \\
&\quad \left. < -C_1 n^{1/2-2\psi}\right) \\
&\leq P\left(\|\sqrt{n} \mathbb{P}_n \tilde{\ell}_0\| \|\theta_n^o - \theta_0\| + (\delta_{max} \sqrt{n}/2) \|\theta_n^o - \theta_0\|^2 + \|n^{-1/2} \Delta_n(\theta_n^o)\| \right. \\
&\quad \left. > C_1 n^{1/2-2\psi}\right) \\
&\leq P\left(\|\sqrt{n} \mathbb{P}_n \tilde{\ell}_0\| > \frac{C_1 - \delta_{max} M^2/2}{M} n^{1/2-\psi} + o_P(n^{1/2-\psi})\right) \\
&\leq \bar{I},
\end{aligned}$$

where δ_{max} is the largest eigenvalue of \tilde{I}_0 , and the second inequality follows from the definitions of \mathcal{N}_n and Δ_n , and the range that $2r > 1/2 \geq \psi > 0$. Denote $\theta_n^* = \arg \max_{\mathcal{N}_n^c} \hat{S}_n(\theta)$. We will show $II \rightarrow 0$ by first decomposing it as $II_1 + II_2$, where

$$\begin{aligned} II_1 &= P \left(n^{-1/2} (\hat{S}_n(\theta_n^*) - \hat{S}_n(\theta_0)) \geq -C_1 n^{1/2-2\psi} \cap \{\theta_n^* \text{ is consistent}\} \right), \\ II_2 &= P \left((\hat{S}_n(\theta_n^*) - \hat{S}_n(\theta_0)) \geq -C_1 n^{1-2\psi} \cap \{\theta_n^* \text{ is inconsistent}\} \right). \end{aligned}$$

Note that we can write $n^{-1/2} \Delta_n(\theta_n^*)$ as $\sqrt{n} \|\theta_n^* - \theta_0\|^2 \epsilon_{1n} + \sqrt{n} \|\theta_n^* - \theta_0\| \epsilon_{2n}$, where $\epsilon_{1n} = o_P(1)$ and $\epsilon_{2n} = o_P(n^{-1/2})$, in the event that $\{\theta_n^* \text{ is consistent}\}$.

Thus, according to (58), we can write II_1 as

$$\begin{aligned} & P \left((\theta_n^* - \theta_0)' \sqrt{n} \mathbb{P}_n \tilde{\ell}_0 + \sqrt{n} \|\theta_n^* - \theta_0\| \epsilon_{2n} \geq \frac{\sqrt{n}}{2} (\theta_n^* - \theta_0)' \tilde{I}_0 (\theta_n^* - \theta_0) \right. \\ & \quad \left. - \sqrt{n} \|\theta_n^* - \theta_0\|^2 \epsilon_{1n} - C_1 n^{1/2-2\psi} \right) \\ & \leq P \left(\|\theta_n^* - \theta_0\| \left[\|\sqrt{n} \mathbb{P}_n \tilde{\ell}_0\| + \sqrt{n} \epsilon_{2n} \right] \geq \frac{\sqrt{n}}{2} \|\theta_n^* - \theta_0\|^2 \delta_{min} \right. \\ & \quad \left. - \sqrt{n} \|\theta_n^* - \theta_0\|^2 \epsilon_{1n} - C_1 n^{1/2-2\psi} \right) \\ & \leq P \left(\left[\|\sqrt{n} \mathbb{P}_n \tilde{\ell}_0\| + \sqrt{n} \epsilon_{2n} \right] \geq \sqrt{n} \|\theta_n^* - \theta_0\| (\delta_{min}/2 - \epsilon_{1n}) - \frac{C_1 n^{1/2-\psi}}{K} \right) \\ & \leq P \left(\left[\|\sqrt{n} \mathbb{P}_n \tilde{\ell}_0\| + \sqrt{n} \epsilon_{2n} \right] \geq \frac{\delta_{min} K^2/2 - C_1}{K} n^{1/2-\psi} + o_P(n^{1/2-\psi}) \right) \\ & \leq \bar{II}_1, \end{aligned}$$

where $\delta_{min} > 0$ is the smallest eigenvalue of \tilde{I}_0 . All the above inequalities follow from the fact that $\|\theta_n^* - \theta_0\| \geq K n^{-\psi}$ for some $K > M$ and $\epsilon_{1n} = o_P(1)$. The term II_2 is shown to converge to zero by the following contradiction arguments. By assuming that the event $\{(\hat{S}_n(\theta_n^D) - \hat{S}_n(\theta_0)) \geq -C_1 n^{1-2\psi}\}$ holds, we have $|\hat{S}_n(\theta_n^D) - \hat{S}_n(\hat{\theta}_n)| = \hat{S}_n(\hat{\theta}_n) - \hat{S}_n(\theta_n^D) \leq \hat{S}_n(\hat{\theta}_n) - \hat{S}_n(\theta_0) + C_1 n^{1-2\psi}$. Note that (58) and the consistency of $\hat{\theta}_n$ implies $\hat{S}_n(\theta_0) - \hat{S}_n(\hat{\theta}_n) =$

$o_P(n)$. Then, we can show that $|\widehat{S}_n(\theta_n^D) - \widehat{S}_n(\widehat{\theta}_n)|/n = o_P(1)$ which implies that θ_n^D is consistent by (57). This implication contradicts with another event in II_2 , i.e., $\{\theta_n^D \text{ is inconsistent}\}$. Therefore we can claim that $II_2 \rightarrow 0$.

In view of the above discussions, it remains to show that \bar{I} and \bar{II}_1 converge to zero. Note that $\|\sqrt{n}\mathbb{P}_n\tilde{\ell}_0\|$ in \bar{I} is $O_P(1)$, and so is $(\|\sqrt{n}\mathbb{P}_n\tilde{\ell}_0\| + \sqrt{n}\epsilon_{2n})$ in \bar{II}_1 . Therefore, by choosing sufficiently large C_1 and $K > M$, meanwhile keeping the inequality $\delta_{max}M^2 < 2C_1 < \delta_{min}K^2$ valid, we show that \bar{I} and \bar{II}_1 can be arbitrarily close to zero. For example, we can take $K = M + B$ and $C_1 = (\delta_{max}M^2 + \delta_{min}(M + B)^2)/4$ for some fixed $B > 0$ and sufficiently large M . This completes the proof of (59).

Our proof of (60) is similar as that of (59). Denote θ_{iS} as an element in \mathcal{S}_n . Similarly, we have

$$\begin{aligned}
P(\theta_n^S \in \mathcal{N}_n^c) &\leq E \{P(\theta_n^S \in \mathcal{N}_n^c \text{ and } \theta_{iS} \in \mathcal{N}_n \text{ for some } i|\mathcal{S}_n)\} \\
&\quad + E \{P(\theta_{iS} \in \mathcal{N}_n^c \text{ for all } i|\mathcal{S}_n)\} \\
&\leq P\left(\max_{\mathcal{S}_n \cap \mathcal{N}_n} \widehat{S}_n(\theta) \leq \max_{\mathcal{S}_n \cap \mathcal{N}_n^c} \widehat{S}_n(\theta)\right) + P(\theta_{iS} \in \mathcal{N}_n^c \text{ for all } i) \\
&\leq P\left(\max_{\mathcal{S}_n \cap \mathcal{N}_n} n^{-1/2}(\widehat{S}_n(\theta) - \widehat{S}_n(\theta_0)) < -C_2 n^{1/2-2\psi}\right) \\
&\quad + P\left(\max_{\mathcal{S}_n \cap \mathcal{N}_n^c} n^{-1/2}(\widehat{S}_n(\theta) - \widehat{S}_n(\theta_0)) \geq -C_2 n^{1/2-2\psi}\right) \\
&\quad + P(\theta_{iS} \in \mathcal{N}_n^c \text{ for all } i) \\
&\leq P\left(\max_{\mathcal{S}_n \cap \mathcal{N}_n} n^{-1/2}(\widehat{S}_n(\theta) - \widehat{S}_n(\theta_0)) < -C_2 n^{1/2-2\psi}\right. \\
&\quad \left.\cap \{\theta_n^\dagger \text{ is consistent}\}\right) \\
&\quad + P\left(\max_{\mathcal{N}_n^c} n^{-1/2}(\widehat{S}_n(\theta) - \widehat{S}_n(\theta_0)) \geq -C_2 n^{1/2-2\psi}\right) \\
&\quad + P(\theta_n^\dagger \text{ is inconsistent}) + P(\theta_{iS} \in \mathcal{N}_n^c \text{ for all } i) \\
&\leq I' + II' + III' + IV',
\end{aligned}$$

where C_2 is an arbitrary positive constant and $\theta_n^\dagger = \arg \max_{\mathcal{S}_n \cap \mathcal{N}_n} \widehat{S}_n(\theta)$.

We first consider the terms III' & IV' . Since $\theta_n^\dagger \in \mathcal{N}_n$, we have $III' \rightarrow 0$ for any M as $n \rightarrow \infty$. The term IV' is computed as

$$(A.49) \quad (1 - P(\bar{\theta} \in \mathcal{N}_n))^{card(\mathcal{S}_n)}.$$

Since the density of $\bar{\theta}$ is assumed to be bounded away from zero around θ_0 and $card(\mathcal{S}_n) \geq \tilde{C}n^\psi$, (A.49) is bounded above by

$$(A.50) \quad \begin{aligned} (1 - \rho n^{-\psi} M)^{card(\mathcal{S}_n)} &\leq (1 - \rho M \tilde{C} / card(\mathcal{S}_n))^{card(\mathcal{S}_n)} \\ &\rightarrow \exp(-\rho M \tilde{C}), \end{aligned}$$

for some $\rho > 0$.

We next consider I' . According to (58), we can show

$$\begin{aligned} &n^{-1/2}(\widehat{S}_n(\theta_n^\dagger) - \widehat{S}_n(\theta_0)) \\ &\geq \max_{\mathcal{S}_n \cap \mathcal{N}_n} \left\{ -\frac{\sqrt{n}}{2}(\theta - \theta_0)' \tilde{I}_0(\theta - \theta_0) \right\} - \max_{\mathcal{S}_n \cap \mathcal{N}_n} \{ -\sqrt{n}(\theta - \theta_0)' \mathbb{P}_n \tilde{\ell}_0 - \Delta_n(\theta) / \sqrt{n} \} \\ &\geq -\min_{\mathcal{S}_n \cap \mathcal{N}_n} \left\{ \frac{\sqrt{n}}{2}(\theta - \theta_0)' \tilde{I}_0(\theta - \theta_0) \right\} - \max_{\mathcal{S}_n \cap \mathcal{N}_n} \{ -\sqrt{n}(\theta - \theta_0)' \mathbb{P}_n \tilde{\ell}_0 - \Delta_n(\theta) / \sqrt{n} \}. \end{aligned}$$

Therefore, we can bound I' by $I'_1 + I'_2$, where

$$\begin{aligned} I'_1 &= P \left(\max_{\mathcal{S}_n \cap \mathcal{N}_n} \{ -\sqrt{n}(\theta - \theta_0)' \mathbb{P}_n \tilde{\ell}_0 - n^{-1/2} \Delta_n(\theta) \} > (C_2/2)n^{1/2-2\psi} \right), \\ I'_2 &= P \left(\min_{\mathcal{S}_n \cap \mathcal{N}_n} \{ \sqrt{n}(\theta - \theta_0)' \tilde{I}_0(\theta - \theta_0) \} > C_2 n^{1/2-2\psi} \right). \end{aligned}$$

Given sufficiently large C_2/M , I'_1 can be arbitrarily close to zero since

$$(A.51) \quad \begin{aligned} I'_1 &\leq P \left(\|\sqrt{n} \mathbb{P}_n \tilde{\ell}_0\| > \frac{C_2}{2M} n^{1/2-\psi} + O_P(n^{1/2-2\psi} \vee n^{1/2-2r}) \right) \\ &\leq P \left(\|\sqrt{n} \mathbb{P}_n \tilde{\ell}_0\| > \frac{C_2}{2M} n^{1/2-\psi} + o_P(n^{1/2-\psi}) \right), \end{aligned}$$

where the last inequality follows from the assumption that $2r > 1/2 \geq \psi$. Since $\min_{\mathcal{N}_n^c} \{\sqrt{n}(\theta - \theta_0)' \tilde{I}_0(\theta - \theta_0)\} > C_2 n^{1/2-2\psi}$ by choosing $\delta_{\min} M^2 > C_2$, I'_2 is bounded above by

$$\begin{aligned}
& P \left(\min_{\mathcal{S}_n} \{\sqrt{n}(\theta - \theta_0)' \tilde{I}_0(\theta - \theta_0)\} > C_2 n^{1/2-2\psi} \right) \\
& \leq \left[P(\sqrt{n}(\bar{\theta} - \theta_0)' \tilde{I}_0(\bar{\theta} - \theta_0) > C_2 n^{1/2-2\psi}) \right]^{card(\mathcal{S}_n)} \\
& \leq \left[1 - P(\|\bar{\theta} - \theta_0\| \leq (C_2/\delta_{max})^{1/2} n^{-\psi}) \right]^{card(\mathcal{S}_n)} \\
& \leq \left[1 - P \left(\|\bar{\theta} - \theta_0\| \leq (C_2/\delta_{max})^{1/2} \tilde{C}/card(\mathcal{S}_n) \right) \right]^{card(\mathcal{S}_n)} \\
& \leq (1 - \rho \tilde{C} (C_2/\delta_{max})^{1/2} / card(\mathcal{S}_n))^{card(\mathcal{S}_n)} \\
(A.52) \quad & \longrightarrow \exp(-\rho \tilde{C} \sqrt{C_2/\delta_{max}})
\end{aligned}$$

for some $\rho > 0$. In the above, the third and fourth inequality follows from the assumptions that $card(\mathcal{S}_n) \geq \tilde{C} n^\psi$ and the density for $\bar{\theta}$ is bounded away from zero around θ_0 , respectively. By assuming that $2C_2 < K^2 \delta_{min}$ for some $K > M$, we can prove that $II' \rightarrow 0$ in the same manner as we show $II \rightarrow 0$.

Let $L = \min\{K^2/2, M^2\}$. In view of (A.50), (A.51), (A.52) and the above discussions on II' , by choosing sufficiently large C_2 , $K > M$ and C_2/M , meanwhile keeping the inequality $C_2 < L\delta_{min}$ valid, we can make $P(\theta_n^S \in \mathcal{N}_n^c)$ arbitrarily small. For example, we can take $C_2 = M^{3/2}\delta_{min}$ and $K = M + B$, for some fixed $B > 0$ and sufficiently large M . This completes the whole proof. \square
